# (54) Anti-Fas recombinant antibodies and DNA therefor

(57) A recombinant protein comprises at least one variable region corresponding to an immunoglobulin variable region specific for human Fas and has substan-

tially no more immunogenicity in a human than a human antibody, and is useful in the treatment of autoimmune diseases, especially rheumalism.

#### Description

The present invention relates to recombinant antibodies directed against Fas, especially human Fas, and to DNA encoding such antibodies. The present invention further relates to pharmaceutical preparations containing such antibodies and being for the treatment of autoimmune diseases including rheumatoid arthritis, the preparations optionally further containing a cell growth inhibitor. The present invention also relates to anti-Fas complementarity determining regions (CDR's) and their use in the creation of such antibodies, and to DNA encoding such CDR's.

The physiological death of cells in a living organism in the natural course of events is known as apoptosis, and is distinguished from the pathological death of cells, i.e. necrosis [c.f. Kerr et al., (1972), Br. J. Cancer, 26, 239 et seq.]. Apoptosis is an example of programmed cell death, which is where certain cells are programmed in advance to die in a living organism in the natural course of events, such as when the cell in question has performed a pre-determined function. Apoptosis is characterised by such morphological changes as curved cell surface, condensed nuclear chromatin and fragmented chromosomal DNA, amongst others.

Apoptosis has an important rôle to play in disposing of cells that recognise autoantigen during the process of T and B lymphocyte differentiation. Onset of so-called autoimmune diseases is generally brought on by the appearance of auto-reactive lymphocytes resulting from the failure of apoptosis during lymphocyte differentiation [c.f. Keiichi Nakayama et al., (1995), Mebio 12(10), 79-86].

Fas is a cell membrane molecule involved in apoptosis of immunocompetent cells [c.f. Yonehara, S., et al. (1989), J. Exp. Med. 169, 1747 et seq., Trauth, B. C., et al. (1989), Science 24, 301 et seq., and Itoh, N., et al., infra]. Murine monoclonal antibodies have been generated against the human Fas antigen [c.f. Itoh, N., et al. (1991), Cell 66, 233-243 and Yonehara, supra, who discloses a monoclonal antibody designated CH11 specific for human Fas]. These antihuman Fas antibodies have apoptosis-inducing cytotoxic activity, and have been proposed as potential therapeutic agents for autoimmune diseases, such as AIDS, as well as tumours [c.f. Japanese Unexamined Patent Publication No. Hei 2-237935 and Japanese Unexamined PCT Publication No. Hei 5-503281]. Ogasawara et al. [Nature (1993), 364, B06-809] report that murine anti-Fas antibodies rapidly kill wild-type mice, evidently by massive apoptosis in the liver.

Monoclonal antibodies against human Fas are also known from the following publications: J. Exp. Med. (1989), 169, 1747-1756; WO 91/10448; Science (1989), 245, 301-305; Cell (1991), 66, 233-243; J. Imm. (1992), 149, 3166-3173; and Internat. Immun. (1994), 6, (12) 1849-1856.

Rheumatism, especially rheumatoid arthritis, is believed to result from the proliferation of synoviocytes, accompanied by a variety of immunological abnormalities. The proliferation of synoviocytes is typically accompanied by inflammatory cellular infiltration and erosion of bone. Tissue erosion around the affected joint in chronic rheumatoid arthritis is apparently caused by abnormal production of cytokines from inflammatory synoviocytes. Examination of joints in patients with rheumatism reveals abnormal proliferation of synoviocytes, hyperplasia of synovial villi, multi-layered synoviocytes, etc. [c.f. Daniel J. McCarty (1985), in "Arthritis and allied conditions, A textbook of rheumatology" 10th Edition, Lea & Febiger]. Medication for rheumatism currently predominantly comprises anti-inflammatory drugs such as steroids and immunomodulators. If it were possible to inhibit abnormal proliferation of synoviocytes, then any such agent should be useful in the therapy of rheumatism.

Synoviocytes in rheumatism do not proliferate in an unlimited manner [c.f. Daniel J. McCarty (1985), in "Arthritis and allied conditions, A textbook of rheumatology" 10th Edition, Lea & Febiger], and it has been demonstrated that apoptosis occurs in the synoviocytes of patients with rheumatism Fas antigen is expressed on the membrane of synoviocytes and Nakajima et al. [Nakajima, T., et al. (1995), Arthritis Rheum. 38, 485-491] and Aono et al. [Abstracts of the 38th Meeting of Japan Rheumatism Society (1994), p. 487, and articles of 1994 Meeting of Japan Cancer Society, (1994), p. 388] investigated whether cytotoxic anti-human Fas antibodies could induce apoptosis in abnormally proliferated synoviocytes from patients with rheumatism. They were able to induce high levels of apoptosis in abnormally proliferated synoviocytes from patients with rheumatism, compared with a control comprising synoviocytes from patients with diseases other than rheumatism.

Thus, anti-human Fas antibody is able to selectively induce apoptosis not only in lymphocytes but also in abnormally proliferated synoviocytes, so that anti-human Fas antibody should be useful as an antirheumatic agent.

However, administration of murine monoclonal antibodies to humans as a pharmaceutical preparation intended for chronic administration is highly likely to cause a variety of problems, owing to the antigenicity arising from the murine origin. Anaphylactic shock is likely to occur, and repeated dosage may reduce efficacy or hasten reduction in blood levels etc., which effects are undesirable if the antibody is to be used in clinical practices.

Efforts to overcome the problems associated with murine monoclonal antibodies have involved the use of recombinant DNA technology in order to obtain a chimaeric antibody wherein the constant region of the mouse antibody has been replaced with the constant region of the corresponding human antibody [c.f. Morrison, S. L., et al. (1984), Proc. Natl. Acad. Sci. USA, 81, 6851-6855]. In an alternative process of humanisation of the murine antibody, the murine CDR present in the variable region of mouse antibody [c.f. Jones, P. T., et al. (1986), Nature, 321, 522-525] has been

inserted into human antibody in an essentially equivalent process. In order to prepare such a genetically engineered antibody, it is first necessary to clone DNA encoding both the H and the L chain subunits which constitute the mouse antibody. These chains specifically recognise the target antigen, so that elucidation of their sequences reveals the primary structure of the variable region containing the CDR, and this can then be used in the preparation of a humanised antibody.

To date, there has been no disclosure of any part of the CDR of a cytotoxic mouse anti-human Fas monoclonal antibody, or of a DNA sequence therefor.

Thus, in a first aspect, the present invention provides a recombinant protein, the protein comprising at least one region corresponding to an immunoglobulin variable region, wherein the at least one region enables the protein to recognise and specifically bind to an antigen, the antigen being human Fas, and wherein the protein has substantially no more immunogenicity in a human patient than a human antibody.

Thus, it will be appreciated that the present invention allows the construction of humanised antibodies specific for human Fas from variable regions recognising human Fas.

As used herein, the term "recombinant" relates to any substance which has been obtained by genetic engineering, insofar as the substance in question is either modified from the original substance, or expressed in a different manner or in a different system than the original.

The term "protein" relates generally to any sequence of amino acid residues linked by peptide bridges, and may encompass oligopeptides as well as polypeptides and multimeric peptide or polypeptide assemblies.

The region corresponding to an immunoglobulin variable region has a structure characteristic of an immunoglobulin variable region, and may correspond to the variable region of either the H chain or the L chain of an immunoglobulin. In the preferred embodiments, the proteins of the present invention have at least two such regions, one corresponding to an H chain variable region, and one corresponding to an L chain variable region, both of which are specific for human Fas.

The proteins of the present invention have substantially no more immunogenicity in a human patient than a human antibody, owing to the fact that the part of the antibody corresponding to a heterologous constant region is not present. Thus, the proteins of the present invention may have a variable region or regions originating from a murine monoclonal antibody, but the murine constant region has been eliminated. As a result, the proteins of the invention only have the same level of immunogenicity as, for example, a human antibody from an alternative source to the patient, owing to the fact that murine variable regions are sufficiently similar to those of humans, that any raised level of immunogenicity can only come from any other amino acid sequence of which the variable region(s) is a part.

The variable regions of the present invention may derive from any source from which it is possible to generate antibodies against human Fas. Although this is most conveniently the mouse, other sources, such as rats and rabbits, are also possible, although these and higher animals tend to be less convenient.

The variable regions of the present invention may be present in the protein in any suitable configuration. At its simplest, the protein may consist essentially of only one variable region, although the efficacy of such proteins tends to be greatly reduced. In part, this is due to lack of stabilisation of the tertiary structure, although binding may still be observed.

At a higher level, the protein may consist essentially of one H chain variable region and one L chain variable region together in association. Such association may be by direct linkage, or may be in the form of a flexible peptide linkage involving one or more extra amino acid residues. Such constructs have the advantage that they do not have any extra peptide sequence to give rise to potential immunogenicity.

Although it is possible for proteins of the present invention to only have one variable region, it is preferred that they have at least two. Further, it is preferred that the two are derived from one particular antibody, such as CH11, one each from the H and L chains, thereby to more closely emulate a natural antibody. In this respect, it is desirable that the variable sequences are integrally bound with human constant regions, especially the appropriate constant regions from the H and L chains.

In the above embodiment, it is preferred that the two variable regions are each respectively a part of a larger polypeptide and the two polypeptides are able to associate to form an antibody heterodimer.

The nature of the antibody is not crucial to the present invention, and may be of any appropriate type, where the protein of the invention actually corresponds to an antibody type. For example, the type may be IgG, IgM or IgE, and the type may be entirely dependent on administration path, for example. Although CH11 is an IgM molecule, the variable regions can just as well be put into an IgG construct. In fact, we have discovered that, if an IgM type construct is used, but without the J chain, which forms a pentameric antibody structure with 5 heavy and light chain pairs, then apoptotic activity is increased by five-fold or even more:

0

It will be appreciated that the present invention further provides DNA and RNA encoding any of the above identified proteins, especially DNA, the DNA may simply encode the protein, or may encode a particular polypeptide, if the protein is heterodimeric, for example.

It will also be appreciated that the DNA may be in any suitable form, so that it may be incorporated into a vector,

suitably an expression vector. It may also be associated with any other suitable sequences, such as leader sequences or sequences for the expression of the encoded protein in the form of a fusion protein, for example.

The present invention further envisages a host cell transformed with a vector as defined above, and a system for the expression of a protein of the invention comprising such a host cell transformed with one or more expression vectors containing the above DNA. The protein of the invention may be obtained from such systems, after cultivation of the system, by standard techniques.

Certain preferred aspects and embodiments of the present invention now follow:

10

15

20

35

40

50

A genetically engineered immunoglobulin protein which specifically binds to human Fas, wherein the immunoglobulin protein consists essentially of an H chain subunit and an L chain subunit, the H chain subunit comprising an amino acid sequence represented by the following general formula (I):

wherein FRH<sub>1</sub> represents an amino acid sequence comprising 13 to 30 amino acid residues, CDRH<sub>1</sub> represents the amino acid sequence of SEQ ID NO. 1, FRH<sub>2</sub> represents an amino acid sequence comprising 14 amino acid residues, CDRH<sub>2</sub> represents the amino acid sequence of SEQ ID NO. 2, FRH<sub>3</sub> represents an amino acid sequence comprising 32 amino acid residues, CDRH<sub>3</sub> represents the amino acid sequence of SEQ ID NO. 3, and FRH<sub>4</sub> represents an amino acid sequence comprising 11 amino acid residues, each of the amino acid sequences being linked to the next *via* a peptide bond;

the L chain subunit comprising an amino acid sequence represented by the following general formula (II):

$$-FRL_{1}-CDRL_{1}-FRL_{2}-CDRL_{2}-FRL_{3}-CDRL_{3}-FRL_{4}- \tag{II}$$

wherein FRL<sub>1</sub> represents an amino acid sequence comprising 23 amino acid residues, CDRL<sub>1</sub> represents the amino acid sequence of SEQ ID NO. 4, FRL<sub>2</sub> represents an amino acid sequence comprising 15 amino acid residues, CDRL<sub>2</sub> represents the amino acid sequence of SEQ ID NO. 5, FRL<sub>3</sub> represents an amino acid sequence comprising 32 amino acid residues, CDRL<sub>3</sub> represents the amino acid sequence of SEQ ID NO. 6, and FRL<sub>4</sub> represents an amino acid sequence comprising 10 amino acid residues, each of the amino acid sequences being linked to the next *via* a peptide bond

The above protein is preferred, when the H chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 116 in SEQ ID NO. 8, and/or wherein the L chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 112 in SEQ ID NO. 10.

The above protein is more preferred when the H chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 571 in SEQ ID NO. 8, and/or the L chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 219 in SEQ ID NO. 10.

The invention further provides DNA encoding an H chain subunit comprising a peptide of formula (I) as defined above. We prefer such DNA when it comprises the nucleotide sequence represented by nucleotides No. 58 to 405 in SEQ ID NO. 7.

Also preferred is DNA which hybridises with such DNA, the sense strand encoding an immunoglobulin H chain subunit capable of specifically binding human Fas together with an L chain subunit comprising an amino acid sequence of general formula (II). It is preferred that such DNA is able to hybridise at 60 to 70°C and in 6 x SSC.

DNA coding for an L chain subunit comprising an amino acid sequence represented by general formula (II) is also preferred, especially where it comprises the nucleotide sequence represented by nucleotides No. 58 to 393 in SEQ ID NO. 9. DNA which hybridises such DNA and whose corresponding sense strand encodes an immunoglobulin L chain subunit which specifically binds to human Fas antigen together with an H chain subunit as defined above which comprises an amino acid sequence of general formula (I) is also preferred, especially where hybridisation is at 60 to 70°C in 6 x SSC.

Further preferred is a recombinant DNA vector containing any of the DNA described above, particularly recombinant DNA vectors pCR3-H123 and pCR3-L103, cells transformed with such vectors and especially *E. coli* pCR3-H123 (FERM BP-5247) and *E. coli* pCR3-L103 (FERM BP-5248).

A preferred method for producing an immunoglobulin protein which specifically recognises human Fas antigen comprises:

culturing a cell transformed by a DNA vector described above under conditions which enable expression of DNA encoding the immunoglobulin H chain or L chain subunit contained in the vector, and recovering the immunoglobulin protein from the culture.

The present invention further envisages the use of CDR's, whether or not linked by framework regions (FR's) as identified above, and DNA encoding such, in the construction of humanised antibodies and proteins in general, which selectively bind human Fas.

Essentially, we have now successfully cloned the genes encoding each of the H, L and J chains of an anti-human Fas, IgM monoclonal antibody. A cDNA library prepared from a hybridoma producing the antibody was used, and it was possible to elucidate the entire nucleotide sequence of each gene and their corresponding amino acid sequences. From these, it was possible to obtain the CDR sequences of the H and L chains. Expression vectors comprising the H, L and J chains were constructed, and it was found that cytotoxic proteins having similar activity to anti-human Fas antibody were obtainable from the supernatant of a culture obtained by co-transfecting cultured animal cells with these vectors.

The DNA of the present invention may be obtained by first preparing poly(A)+ RNA from mouse hybridoma cells producing anti-human Fas monoclonal antibody, such as CH11. The poly(A)+ RNA may then be converted to cDNA using a reverse transcriptase, and purifying the cDNA encoding the H, L and, optionally, the J chains of the antibody. Yonehara et al. [(1989), J. Exp. Med. 169, 1747 et seq.] obtained an anti-human Fas monoclonal antibody, which was designated CH11, by fusion of mouse myeloma cells with mouse lymphocytes after the mice had been immunised with the Fas-expressing human diploid fibroblast cell-line FS-7. The CH11 antibody is commercially available from Medical Biological Laboratory Co. Ltd. of Japan.

Poly(A)+ RNA may be obtained either by first preparing total RNA and then purifying poly(A)+ RNA from the total RNA using, for example an affinity column packed with oligo(dT) cellulose, oligo(dT) latex beads etc., or it may be obtained by directly purifying poly(A)+ RNA from cell lysates using such affinity materials as described above. Total-RNA may be prepared, for example, by such methods as: alkaline sucrose density gradient ultracentrifugation [c.f. Dougherty, W. G. and Hiebert, E., (1980), Virology, 101, 466-474]; the guanidine thiocyanate-phenol method; the guanidine thiocyanate-trifluorocaesium method; and the phenol-SDS method. The preferred method, however, employs guanidine thiocyanate and caesium chloride [c.f. Chirgwin, J. M., et al. (1979), Biochemistry, 18, 5294-5299].

The single stranded (ss) cDNA obtained by the use of reverse transcriptase, as described above, can then be converted to double stranded (ds) cDNA. Suitable methods for obtaining the ds cDNA include the S1 nuclease method [c.f. Eistratiadis, A., et al. (1976), Cell, 7,279-288] and the Gubler-Hoffman method [c.f. Gubler, U. and Hoffman, B. J. (1983), Gene, 25, 263-269]. However, we prefer to employ the Okayama-Berg method [c.f. Okayama, H. and Berg, P. (1982), Mol. Cell. Biol. 2, 161-170].

The ds cDNA obtained above may then be integrated into a cloning vector and the resulting recombinant vector can then be used to transform a suitable microorganism, such as *E. coli*. The transformant can be selected using a standard method, such as by selecting for tetracycline resistance or ampicillin resistance encoded by the recombinant vector. If *E. coli* is used, then transformation may be effected by the Hanahan method [*c.f.* Hanahan, D. (1983), J. Mol. Biol., 166, 557-580]. Alternatively, the recombinant vector may be introduced into competent cells prepared by coexposure to calcium chloride and either magnesium chloride or rubidium chloride. If a plasmid is used as a vector, then it is highly desirable that the plasmid harbours a drug-resistant gene, such as mentioned above, in order to facilitate selection. Brute force selection is possible, but not preferred. Although plasmids have been discussed, it will be appreciated that other cloning vehicles, such as lambda phages, may be used.

Methods for selecting transformants having the desired DNA include the following:

#### (1) Screening using a synthetic oligonucleotide probe

If all or part of the amino acid sequence of the desired protein has been elucidated, then a short contiguous sequence, which is also representative of the desired protein, may be used to construct an oligonucleotide probe. The probe encodes the amino acid sequence but, owing to the degeneracy of the genetic code, there may be a large number of probes that can be prepared. Thus, an amino acid sequence will normally be selected which can only be encoded by a limited number of oligonucleotides. The number of oligonucleotides which it is necessary to produce can be further reduced by the substitution of inosine where any of the four normal bases can be used. The probe is then suitably labelled, such as with <sup>32</sup>P, <sup>35</sup>S or biotin, and is then hybridised with denatured, transformed DNA from the transformant which has been immobilised on a nitrocellulose filter. Positive strains show up by detection of the label on the probe.

#### (2) Polymerase Chain Reaction

25

If all or part of the amino acid sequence of the desired protein has been elucidated, then sense and antisense oligonucleotide primers corresponding to separate non-contiguous parts of the amino acid sequence can be synthesised, such as by the methods described in (1) above. These primers can then be used in the polymerase chain reaction technique [c.f. Saiki, R. K., et al. (1988), Science, 239, 487-491] using the template DNA. The template DNA used

herein may be cDNA synthesised by a reverse transcriptase reaction using mRNA obtained from a hybridoma producing anti-human Fas antibody, such as that which expresses CH11. The DNA fragment thus synthesised may either be directly integrated into a plasmid vector, such as by using a commercial kit, or may be labelled with, for example, <sup>32</sup>P, <sup>35</sup>S or biotin, and then used as a probe for colony hybridisation or plaque hybridisation to obtain the desired clone.

Monoclonal antibody CH11 is an immunoglobulin M ("IgM") molecule, a complex comprising five subunits each of the H (μ chain) and L chains, and one J chain. Thus, in order to elucidate partial amino acid sequences for the subunits, the subunits must be separated, and this can be done using any suitable technique, such as electrophoresis, column chromatography, etc. well known to those skilled in the art. Once the subunits have been separated, they can be sequenced, such as by the use of an automatic protein sequencer (for example, PPSQ-10 of Shimadzu), in order to determine the amino acid sequence of at least the N-terminal of each subunit. Oligonucleotides/primers can then be produced using this knowledge.

Harvesting of DNA encoding each subunit of anti-human Fas monoclonal antibody from the appropriate transformants obtained above may be performed by well known techniques, such as those described by Maniatis, T., et al. [in "Molecular Cloning A Laboratory Manual" Cold Spring Harbor Laboratory, NY, (1982)]. For example, the region of DNA coding for the desired subunit may be excised from plasmid DNA after separating the fraction corresponding to the vector DNA from a transformant which has been determined to possess the necessary plasmid.

*E. coli* DH5α has been transformed with plasmids containing DNA encoding the heavy, light and J chains of CH11, prepared as described above, and the resulting three transformants (designated *E. coli* pCR3-H123, *E. coli* pCR3-L103 and *E. coli* pCR3-J1123, respectively) have been deposited in accordance with the terms of the Budapest Treaty on the Deposition of Microorganisms at the Research Institute of Life Science Technology of the Agency of Industrial Science and Technology on February 28, 1996, and have been allocated deposit Nos. FERM BP-5427, FERM BP-5428 and FERM BP-5429, respectively. *E. coli* DH5α containing these plasmids may be cultivated in a directly comparable manner to *E. coli* DH5α not possessing these plasmids. All deposited strains may be selected by their resistance to ampicillin. The DNA of the present invention, therefore, may be obtained using these deposits. This can be done, for example, either by cultivating the deposits and isolating the plasmids, or by using the polymerase chain reaction (PCR) using the plasmids as templates.

Wherever appropriate, DNA sequences may be sequenced in accordance by various well known methods in the art including, for example, the Maxam-Gilbert chemical modification technique [c.f. Maxam, A. M. and Gilbert, W. (1980) in "Methods in Enzymology" 65, 499-276] and the dideoxy chain termination method using M13 phage [c.f. Messing, J. and Vieira, J. (1982), Gene, 19, 269-276]. In recent years, a further method for sequencing DNA has gained wide acceptance, and involves the use of a fluorogenic dye in place of the conventional radioisotope in the dideoxy method. The whole process is computerised, including the reading of the nucleotide sequence after electrophoresis. Suitable machinery for the process is, for example, the Perkin-Elmer Sequence robot "CATALYST 800" and the Perkin-Elmer model 373A DNA Sequencer. The use of this technique renders the determination of DNA nucleotide sequences both efficient and safe.

Accordingly, from the thus determined nucleotide sequences of the DNA encoding the H and L chains of CH11, in conjunction with the sequence data for the N-termini of the H and L chains, it was possible to determine the entire amino acid sequence of the H and L chains of CH11.

Framework regions (FR's) are present in the variable regions of the H and L chains of immunoglobulins and serve to flank the variable region and to separate the CDR's. Accordingly, there is one more FR compared to the number of CDR's in each variable region. The framework regions also contribute to the three-dimensional structure of the variable region, thereby assisting in antigenic binding by stabilising the tertiary structure of the region. By way of illustration of the terminology applied to each FR and CDR in the variable region, FRH<sub>1</sub> is the framework region at the N-terminal end of the variable region of the H chain. Working towards the C-terminal end, there is, respectively, CDRH<sub>1</sub>, FRH<sub>2</sub>, CDRH<sub>2</sub>, FRH<sub>3</sub>, CDRH<sub>3</sub> and, finally, FRH<sub>4</sub>. A similar nomenclature applies to the L chain, so that the first framework region is designated FRL<sub>1</sub>, etc.

Both immunoglobulin H and L chains comprise a variable region and a constant region. The variable region is composed of CDR's and, as described above, both the H chain and the L chain have three CDR's interconnected and flanked by four framework regions. The amino acid sequences of the constant regions are the same, irrespective of the antigen recognised, and this is true separately for the H and L chains, provided that the immunoglobulin class is the same. By contrast, the amino acid sequence of the variable region, particularly the CDR's, is peculiar to each antibody. However, according to a comparative study on amino acid sequences of a number of antibodies, both the location of the CDR's and the length of the framework sequences connecting them are virtually constant among antibody subunits of the same subgroup [Kabat, E. A., et al. (1991), in "Sequence of Proteins of Immunological Interest Vol. II". U.S. Department of Health and Human Services]. With this knowledge, therefore, it was possible to determine the location of the CDR's, framework regions and the constant region of each of the H and L chains of CH11 by comparison of the amino acid sequences we had determined with the known amino acid sequences.

It will be appreciated that the framework regions are important for separating the CDR's and help in the steric

determination of structure of the variable regions, but that, provided that these requirements are met, then the actual size and sequence of each framework region is not critical to the present invention, given that the FR's are not responsible for binding the antigen. Accordingly, any suitable amino acid sequence can be used for each FR. However, it has been observed that framework regions are commonly conserved in nature and, for this reason, we generally prefer to retain regions which are either identical with or which correspond closely to those found in CH11 (Yonehara et al., supra).

Although the chain lengths of the framework region are generally substantially conserved, especially within immunoglobulin sub-types, it has been established that FRH<sub>1</sub>, located at the N-terminal of the H chain may sometimes be shorter than expected. Thus, instead of 30 amino acids, FRH<sub>1</sub> may be as short as 13 amino acids, in mouse IgM, and a minimum length of 19 amino acids for a  $\mu$  2a subtype for CH11 has been established [c.f. Kabat et al. ibid.]. Accordingly, the chain length of the framework region at the N-terminal of the H chain may be anywhere between 13 and 30 amino acids. This range is preferably from 19 to 30 amino acids and is most preferably 30 amino acids.

In general, it will be appreciated that the framework regions at either end of the variable region (FRH<sub>1</sub> and FRH<sub>4</sub> in the H chain) are of less importance than the interstitial framework regions actually connecting the CDR's (FRH<sub>2</sub> and FRH<sub>3</sub> in the H chain). Accordingly, the flanking framework regions may vary by up to about 60% in length from the norm for any given antibody type, while the interstitial framework regions can vary in length to only a limited extent, which is typically only about one amino acid. In some cases, any variation in length may result in substantially reduced efficiency, and the skilled person in the art will easily be able to establish the requisite parameters for any given variable region construct.

If it is desired to construct an altered sequence in which any one or more amino acids are deleted in the amino acid sequence, then the cassette mutation method may be used, for example [c.f. Toshimitsu Kishimoto, "Shin-Seikagaku Jikken Kouza (New Biochemistry Experiment Series) II: Nucleic Acid III, Recombinant DNA Technology", pp. 242-251].

Any appropriate amino acid sequences may be bound to the C-terminal end of either variable region, provided that they do not adversely affect the antigen-binding ability of the antibody, unless this is for a reason, such as to form a precursor molecule, for example in the form of a leader sequence. In general, where there is a C-terminal sequence, then we prefer that it corresponds to a human constant region from the appropriate H or L chain.

DNA of the present invention may be prepared by any suitable method, such as by chemical synthesis using conventional methods, such as the phosphate-triester method [c.f. Hunkapiller, M., et al. (1984), Nature, 310, 105-111; and Grantham, R., et al. (1981), Nucleic Acids Res. 9, r43-r74]. The various codons for amino acids are well known, and their selection may be totally arbitrary, although it is generally preferred to make the selection based on the frequency of usage of the codons for the selected host. If a technique other than direct chemical synthesis is employed, then it may be desired to partially modify the codons of the sequence obtained, and this can be effected, for example, by site specific mutagenesis [c.f. Mark, D. F., et al. (1984), Proc. Natl. Acad. Sci. USA, 81, 5662-5666] using, as primers, synthetic oligonucleotides incorporating the desired modification.

35

50

In the present invention, where it is specified that DNA can hybridise with other DNA, then this may be established by techniques well known in the art. For example, to establish whether a certain sequence hybridises with any other given sequence, then one or other sequence may be labelled with, for example, [ $\alpha$ - $^{32}$ P] dCTP, using the random primer method [ $\alpha$ - $^{32}$ P] dCTP,

Integration of DNA of the present invention thus obtained into an expression vector allows transformation of prokaryotic or eukaryotic host cells. Such expression vectors will typically contain suitable promoters, replication sites and sequences involved in gene expression, allowing the DNA to be expressed in the host cell.

Suitable prokaryotic host cells include, for example, *E. coli (Escherichia coli)* and *Bacillus subtilis*. In order to express the gene of interest in such host cells, these host cells may be transformed with a plasmid vector containing a replicon derived from a species compatible with the host, typically having an origin of replication and a promoter sequence, such as lac UV5. These vectors preferably have sequences capable of conferring a selection phenotype on the transformed cell.

A suitable strain of E. coli is strain JM109 derived from E. coli K12. Sultable vectors include pBR322 and the pUC series plasmids. Suitable promoters include the lactose promoter (lac) and the tryptophan lactose promoter (trc). In

general, it will be appreciated that the present invention is not limited to the use of such hosts, vectors, promoters, etc., as exemplified herein and that any suitable systems may be used, as desired.

A suitable preferred strain of *Bacillus subtilis* is strain 207-25, and a preferred vector is pTUB228 [c.f. Ohmura, K., et al. (1984), J. Biochem., 95, 87-93]. A suitable promoter is the regulatory sequence of the *Bacillus subtilis*  $\alpha$ -amylase gene. If desired, the DNA sequence encoding the signal peptide sequence of  $\alpha$ -amylase may be linked to the DNA of the present invention to enable extracellular secretion.

Suitable eukaryotic cell hosts include those from vertebrates, yeasts, etc. Suitable vertebrate cells include, for example, the monkey cell line COS [c.f. Gluzman, Y. (1981), Cell, 23, 175-182]. Suitable yeasts include Saccharomyces cerevisiae and Schizosaccharomyces pombe.

In general, the requirements for suitable expression vectors for vertebrate cells are that they comprise: a promoter usually upstream of the gene to be expressed; an RNA splicing site; a polyadenylation site; and a transcription termination sequence, etc. As desired, they may additionally contain, as needed, an origin of replication. A suitable plasmid is pSV2dhfr containing the SV40 early promoter [c.f. Subramani, S., et al. (1981), Mol. Cell. Biol., 1, 854-884].

Suitable eukaryotic microorganisms are the yeasts, such as *S. cerevisiae*, and suitable expression vectors for yeasts include pAH301, pAH82 and YEp51. Suitable vectors contain, for example, the promoter of the alcohol dehydrogenase gene [c.f. Bennetzen, J. L. and Hall, B. D. (1982), J. Biol. Chem., 257, 3018-3025] or of the carboxypeptidase Y GAL10 promoter [c.f. Ichikawa, K., et al. (1993), Biosci. Biotech. Biochem., 57, 1686-1690]. If desired, the DNA sequence encoding the signal peptide sequence of carboxypeptidase Y may be linked to the DNA to be expressed in order to enable extracellular secretion.

20

In the case of COS cells being used as hosts, suitable vectors comprise the SV40 replication origin, enabling autonomous growth, a transcription promoter, a transcription termination signal and an RNA splicing site. The expression vectors can be used to transform the cells by any suitable method, such as the DEAE-dextran method [c.f. Luthman, H, and Magnusson, G. (1983), Nucleic Acids Res., 11, 1295-1308], the phosphate calcium-DNA co-precipitation method [c.f. Graham, F. L. and van der Eb, A. J. (1973), Virology, 52, 456-457] and the electric pulse electroporation method [c.f. Neumann, E., et al. (1982), EMBO J., 1, 841-845]. In a preferred embodiment COS cells are co-transfected with two separate expression vectors - one containing DNA encoding a protein comprising the variable region of the H chain of CH11 and one containing DNA encoding a protein comprising the variable region of the L chain of CH11, these vectors being expressed simultaneously to generate a recombinant anti-human Fas antibody.

Transformants of the present invention may be cultured using conventional methods, the desired proteins being expressed either intra- or extra- cellularly. Suitable culture media include various commonly used media, and will generally be selected according to the host chosen. For example, suitable media for COS cells include RPMI-1640 and Dulbecco's Modified Eagle Minimum Essential medium which can be supplemented with, as desired, foetal bovine serum (FBS). The culture temperature may be any suitable temperature which does not markedly depress the protein synthesis capability of the cell, and is preferably in the range of 32 to 42°C, most preferably 37°C, especially for mammalian cells. If desired, culture may be effected in an atmosphere containing 1 to 10% (v/v) carbon dioxide.

The protein expressed by the transformants of the present invention may be isolated and purified by various well known methods of separation according whether the protein is expressed intra- or extra- cellularly and depending on such considerations as the physical and chemical properties of the protein. Suitable specific methods of separation include: treatment with commonly used precipitating agents for protein; various methods of chromatography such as ultrafiltration, molecular sieve chromatography (gel filtration), adsorption chromatography, ion exchange chromatography, affinity chromatography and high performance liquid chromatography (HPLC); dialysis; and combinations thereof.

By the use of such methods as described above, the desired protein can be readily obtained in high yields and high purity. The antibody produced in the preferred embodiment may lack the J chain if there is no extra plasmid encoding the J chain. In such an instance, we have established that the resulting H and L chain heterodimers have a cytotoxicity about five times greater than that of CH11.

The specific binding activity of proteins of the present invention for Fas antigen may be determined, for example, by enzyme-linked immunosorbent assay (ELISA). In one specific embodiment of ELISA, Fas antigen is immobilised on the bottom of wells of a 96-well plate and test protein is introduced to the wells, whereafter the cells are washed to remove unbound protein. After washing, the wells are exposed to an enzyme-labelled antibody specific for the protein, such as the constant region thereof. The cells are then washed again, and any label remaining in the well is detected. cDNA encoding for human Fas antigen has previously been disclosed and methods for introducing the cDNA into animal cells for expression thereof are also known [c.f. Itoh, N., et al. (1991), Cell, 66, 233-243]. Antigen for use in the above ELISA method can be obtained from the culture supernatant of cells which have been transformed with an expression vector containing the gene encoding a fusion protein comprising the extracellular region of the human Fas antigen and the extracellular region of mouse interleukin 3 receptor, as disclosed in Itoh (supra).

Cytotoxicity of the proteins of the present invention can be established, for example, by culturing cells expressing Fas (for example, human lymphocyte cell line HPB-ALL [c.f. Morikawa, S., et al. (1978), Int. J. Cancer, 21, 166-170]

and Jurkat (American Type Culture No. TIB-152)) in medium into which the test sample has been or will be added, and determining the survival ratio by MTT Assay [c.f. Green, L. M., et al. (1984), J. Immunological Methods, 70, 257-268).

Using the DNA of the present invention, chimaeric mouse antibody wherein the constant regions have been replaced with those of human immunoglobulin [c.f. Morrison, S. L., et al. (1984), Proc. Natl. Acad. Sci. USA, 81, 6851-6855] can be constructed.

Likewise, it is possible to construct an Fv fraction composed essentially only of the variable regions of the H and L chains, this being a single chain Fv (scFv) [c.f. Huston, J. S., et al. (1988), Proc. Natl. Acad. Sci. USA, 85, 5879 et seq.] wherein the H and L chains are linked by a flexible peptide.

Thus, in accordance with the present invention, anti-Fas antibody having a reduced immunogenicity in humans may be produced by constructing a humanised antibody comprising the constant regions of human antibody with the CDR's of a murine human anti-Fas antibody [c.f. Jones, P. T., et al. (1986), Nature, 321, 522-525].

The present invention also provides methods and therapeutic compositions for treating the conditions referred to above. Such compositions typically comprise a therapeutically effective amount of the protein of the present invention in admixture with a pharmaceutically acceptable carrier therefor. The composition may be administered in any suitable manner, such as by parenteral, intravenous, subcutaneous or topical administration. In particular, where the condition to be treated is local, then it is preferred to administer the protein as close as possible to the site. For example, serious rheumatic pain may be experienced in major joints, and the protein may be administered at such locations. Systemically administered proteins of the present invention are particularly preferably administered in the form of a pyrogen-free, therapeutically, particularly parenterally, acceptable aqueous solution. The preparation of such pharmaceutically acceptable protein solutions with regard to aspects such as pH, isotonicity, stability and the like, is well within the skill of the person skilled in the art. In addition, the compositions of the present invention may comprise such further ingredients as may be deemed appropriate, such as cell growth retardants and other medicaments.

The dosage regimen for the various conditions treatable with the proteins of the present invention will be readily apparent to one skilled in the art, taking into account various factors, such as the condition, body weight, sex and diet of the patient, the severity of any symptoms, time, the desirability of repeat treatment, as well as any other appropriate clinical factors. As a general guide, the daily dose should typically be in the range of 1 - 1000 µg protein per kilogram of body weight.

The invention will now be explained in more detail with reference to the following Examples, the Examples being illustrative of, but not binding on, the present invention. Any methods, preparations solutions and such like which are not specifically defined may be found in 'Molecular cloning - A Laboratory Handbook' (supra). All solutions are aqueous and made up in sterile, deionised water, unless otherwise specified.

#### **EXAMPLE 1**

Cloning of DNA Encoding the Variable Region of Mouse Monoclonal Antibody CH11 against the Human Fas Antigen

#### (1-1) Preparation of poly(A)+RNA

Total RNA was prepared from a CH11-producing hybridoma (obtained from Yonehara, *supra*) in accordance with the method described by Chirgwin and co-workers [see Chirgwin, J. M., *et al.*, (1979) Biochemistry 18:5294]. Specifically, the CH11-producing hybridoma [see Yonehara, S., *et al.*, (1994), International Immunology 6, 1849-1856] was cultured in ASF104 medium (Ajinomoto) containing 10% (v/v) foetal bovine serum (Gibco). Approximately 6.7 x 10<sup>8</sup> cells were harvested by centrifugation and the supernatant was discarded. The resulting pellet of cells was then mixed straightaway with 60 ml of 4 M guanidine thiocyanate solution (Fluka). The cells in the resulting suspension were subsequently lysed by aspirating the cell suspension through a syringe equipped with a 21-gauge needle three times. The cell lysate thus obtained was layered onto 3 ml of 5.7 M caesium chloride/0.1 M EDTA solution (pH 7.5) in an ultracentrifugation tube (13PA:Hitachi Koki) and the tube was spun in an Hitachi RPS-40T Rotor (13PA tube, 150,000 x g at 20°C for 18 hours) to precipitate the RNA. The precipitated RNA was dissolved in water, extracted with chloroform/1-butanol (4:1, v/v) and then re-precipitated with 100% ethanol.

Poly (A)\* RNA was purified next from the total, resulting RNA, prepared above, by routine methods [c.f. Maniatis, T. et al., (1988), "Molecular Cloning: A Laboratory Manual" (2nd Edition), Cold Spring Harbor Lab., 7.26 - 7.28]. More specifically, a disposable polystyrene column (diameter 0.7 cm) was packed with 100 mg of oligo dT cellulose (Pharmacia, Type 7). The column was equilibrated with a loading buffer, comprising 20 mM tris-hydrochloric acid (pH 7.6), 0.5 M sodium chloride, 1 mM ethylenediamine tetraacetate (EDTA) and 0.1% (w/v) sodium dodecylsulphate (SDS). Total RNA (approximately 1.2 mg), was then dissolved in a total volume of 400 μl of water by heating at 65°C for 5 minutes, and then 400 μl of loading buffer (made up at double the above concentration) was added to the solution. The resulting mixture was cooled to room temperature and then poured onto the column. The fraction that passed

straight through the column was recovered, heated at 65°C for a further 5 minutes, and poured back onto the column. The column was next washed with 10 ml of loading buffer, and then further washed with 5 ml of loading buffer containing 0.1 M sodium chloride to remove both non-adsorbates and also non-specific adsorbates. Subsequently, 5 ml of elution buffer [10 mM tris-hydrochloric acid (pH 7.5), 1 mM EDTA and 0.05% (w/v) SDS] was poured onto the column in order to elute specific adsorbates. The resulting eluate was recovered in fractions of 200 µl. The third and tourth 200 µl elution fractions (400 µl in total) were combined, and mixed with 40 µl of 3 M sodium acetate (pH 4.0) and 1 ml of ethanol. The resulting mixture was stored at -20°C overnight. The next day the mixture was spun in a centrifuge (10,000 x g, 4°C for 10 minutes) to recover the pellet. This pellet was used as the poly (A)\* RNA sample and was stored at -80°C until it was required for use.

#### (1-2) Cloning of DNA coding for variable regions

cDNA fragments coding for the variable regions of the H chain and L chain of mouse anti-Fas antigen (CH11) were cloned by 'RT-PCR', which combines reverse transcription (using reverse transcriptase -RT) with the polymerase chain reaction (PCR). The combination of these techniques allowed the specific amplification of a desired sequence from the poly(A)+ RNA sample derived from the CH11-producing hybridoma prepared in (1-1).

Two sets of primers for the RT-PCR reaction were selected from the Ig-Prime Set (Novagen). MulgV<sub>H</sub>5'-B and MulgMV<sub>H</sub>3'-1 were used to amplify a region of the H chain, while MulgkV<sub>L</sub>5' and MulgMV<sub>L</sub>3'-1 were used to amplify a region of the L chain. RT-PCR reactions were carried out using both the H chain primer sets and L chain primer sets, respectively.

#### a) Reverse transcriptase reaction

A reverse transcriptase reaction solution (44 µI) was made up as follows. 10 mM tris-hydrochloric acid (pH 8.3), 50 mM potassium chloride, 0.1 mM dATP, 0.1 mM dGTP, 0.1 mM dCTP, 0.1 mM dTTP, 1.5 mM magnesium chloride, 2.5 pmol of H chain or L chain 3'-side primer, 50 ng of the poly (A)\* RNA prepared in (1.1) and 20 units of reverse transcriptase (BIOCHEMICAL KOGYO CO., LTD.) derived from Moloney murine leukaemia virus (MMLV) were combined and the resulting mixture was incubated at 42°C for one hour.

#### b) Amplification by PCR

The reverse transcriptase reaction solution prepared in a) was mixed with 25 pmol of H chain or L chain 5' primer, as appropriate, with 5 units of Taq DNA polymerase (ampliTaq DNA Polymerase obtained from Perkin Elmer, Japan) to a final volume of 100 µl of reaction buffer supplied with kit (buffers and solutions for enzymes are as supplied with supplier's kit, unless otherwise specified). The total, resulting, reaction mixture was heated at 94°C for 2 minutes, and then subjected to a heat cycle of 94°C for one minute, 50°C for one minute and 72°C for 2 minutes. This cycle was repeated 30 times. The solution was then kept at 72°C for a further 10 minutes. A gene amplifier PCR system 9600 (Perkin Elmer, Japan) was used to control the reaction temperature in all of the PCR reactions.

#### c) Assay of PCR product

A portion of the PCR reaction mixture prepared in b) was analysed by gel electrophoresis on a 1.5% (w/v) agarose gel (FMC Bioproducts). The product of each of the H and L chain PCR reactions was obtained as a band of about 430 bp. The band size was estimated by comparing it with molecular weight markers that had also been run on the same gel.

# d) Cloning of PCR product

Each of the PCR products obtained in b) was ligated into separate plasmid vectors using an original TA cloning kit (Invitrogen). More specifically, 50 ng of the pCRII vector and four units of T4 DNA ligase (both included in the kit) were added to a ligase reaction buffer [6 mM tris-hydrochloric acid (pH 7.5), 6 mM magnesium chloride, 5 mM sodium chloride, 7 mM β-mercaptoethanol, 0.1 mM ATP, 2 mM dithiothreitol (DTT), 1 mM spermidine and 0.1 mg/ml bovine serum albumin]. The ligase reaction buffer also contained a portion of the PCR reaction mixture which was selected such that it contained approximately 10 ng of the desired PCR product, as estimated by gel electrophoresis in c) above. The resulting mixture was incubated at 14°C for 15 hours.

Subsequently, 2  $\mu$ l of the ligase reaction mixture was mixed with 50  $\mu$ l of *E. coli*, strain TOP10F' (included in the kit), which had previously been made competent by the addition of 2  $\mu$ l of 0.5 M  $\beta$ -mercaptoethanol. The resulting transformation mixture was placed on ice for 30 minutes, heated at 42°C for 30 seconds and then placed on ice again for a further 2 minutes. After this time, the mixture was then added to 500  $\mu$ l of SOC medium [2% (w/v) tryptone, 0.5%

(w/v) yeast extract, 0.05% (w/v) sodium chloride, 2.5 mM potassium chloride, 1 mM magnesium chloride, 20 mM glucose], and the resulting mixture was cultured with rotational shaking for one hour (37°C, 110 rpm). The resulting culture was then spread onto L-broth agar medium plates [1% (w/v) tryptone, 0.5% (w/v) yeast extract, 0.5% (w/v) sodium chloride, 0.1% (w/v) glucose, 0.6% (w/v) Bacto Agar (Difco)] containing 100 μg/ml of ampicillin and the plates were cultured at 37°C overnight without shaking.

Ampicillin-resistant colonies generated by this procedure were selected and scraped off with platinum picks. Cells from the selected colonies were separately cultured in 5 ml of L-broth medium containing 100 µg/ml of ampicillin, at 37°C, overnight. The cultures were then centrifuged to pellet the cells and plasmid DNA was prepared from the cells using the alkaline lysis method (c.f. Maniatis, T., et al., supra). A plasmid for each of the H and L primer sets was obtained, and these were designated pVH4 (the plasmid containing the fragment amplified using the H chain primer set) and pVL8 (the plasmid containing the fragment amplified using the L chain primer set).

#### **EXAMPLE 2**

10

15

35

- Determination of the Amino Acid Sequence and Nucleotide Sequence of the Variable Regions of CH11
- (2-1) <u>Determination of the N-terminal amino acid sequences of the variable regions of the H chain and L chain</u> of <u>CH11</u>

#### a) Preparation of CH11

The CH11-producing hybridoma (see Example 1) was grown to a cell number of 2 x 10<sup>8</sup> in an ASF 104 medium (Ajinomoto) containing 10% (v/v) of bovine serum (Gibco), and this preparation was then cultured in 50 ml of serum free: ASF 104 medium at 37°C for 5 days. After this time, the culture was centrifuged (Tommy Seiko's No. 4 rotor, 15.000 x g, 4°C for 15 minutes) and the supernatant was collected. CH11 was obtained from the culture supernatant using an E-Z-Sep antibody purification kit (Pharmacia Biotech).

- b) A portion of the purified CH-11, corresponding to 100 μl of the supernatant prepared in a), was added to 10 μl of 100 mM tris-hydrochloric acid buffer (pH 6.8) containing 10% (v/v) of β-mercaptoethanol and 4% (w/v) SDS. The resulting mixture was denatured by heating at 95°C for 5 minutes. The denatured sample was then subjected to electrophoresis on a 12% (w/v) polyacrylamide gel. After electrophoresis the gel was immersed in transfer buffer [25 mM tris-boric acid (pH 9.5), 10% methanol (v/v)] and shaken at room temperature for 15 minutes. The protein bands on the gel were then transferred onto a polyvinylidene difluoride (PVDF) membrane (Nippon Millipore Ltd.), using a semidrive blotting apparatus (Iwaki Glass Co., Ltd.), at a constant current of 0.2 A at 4°C for 1 hour. After this time, the PVDF membrane was stained with a 0.1% (w/v) Coomassie Brilliant Blue solution and destained with 100% methanol. Only two major protein spots were seen, corresponding to the H chain and L chain. These protein spots were excised, and the gel containing them was dried at room temperature.
- c) The amino acid sequence of the proteins transferred onto the PVDF membrane in b) was analysed using a gas phase protein sequencer (PPSQ-10; Shimadzu Corporation) using the automatic Edman method [see Edman, P., et al., (1967), Eur. J. Biochem. 1, 80 et seq.]. The N-terminal amino acid sequence of the variable region of the H chain of CH11, and the N-terminal amino acid sequence of the L chain were thus determined, and are shown as SEQ ID NOs. 13 and 14 of the sequence listing, respectively.

#### (2-2) Determination of DNA nucleotide sequence

The total nucleotide sequences of the cDNA coding for the variable regions of the H and L chains of CH11 were determined by sequencing the inserts in plasmids pVH4 and pVL8 respectively (prepared in Example 1).

The pCRII vector has an SP6 promoter sequence and a T7 promoter sequence, and these flank any inserted cDNA, thus allowing the sequence of the inserts of pVH4 and pVL8 to be determined using oligonucleotide primers (Perkin Elmer, Japan) corresponding to the sequences. Samples for sequence analysis were prepared using these primers and a dye primer cycle-sequencing kit (Perkin Elmer, Japan). Plasmid DNA from plasmids pVH4 or pVL8 was used as a template. The sequence of each cDNA insert was determined using a DNA sequencer (Model 373, Perkin Elmer, Japan). The cDNA nucleotide sequence of the H chain variable region is shown as SEQ ID NO. 15 and the cDNA nucleotide sequence of the L chain variable region is shown as SEQ ID NO. 16.

0

The N-terminal amino acid sequence of the H chain of CH11, represented by amino acid Nos. 1 to 15 of SEQ ID NO. 13 in the sequence listing, corresponds completely to the amino acid sequence encoded by nucleotide Nos. 32

to 76 of SEQ ID NO. 15. Therefore, it was deduced that plasmid pVH4 contains DNA coding for the variable region of the H chain of CH11.

The N-terminal amino acid sequence of the L chain of CH11, represented by amino acid Nos. 1 to 21 of SEQ ID NO. 14 in the sequence listing, corresponds completely to the amino acid sequence encoded by nucleotide Nos. 29 to 91 of SEQ ID NO. 16. Therefore, it was deduced that plasmid pVL8 contains DNA coding for the variable region of the L chain of the CH11.

#### EXAMPLE 3

20

#### Cloning of DNA Encoding the Complete H Chain, L Chain and J Chains of CH11

#### (3-1) Preparation of a cDNA library

A cDNA library was prepared by the Okayama-Berg method [Okayama, H. et al., (1987), Methods in Enzymology 154, 3-28]. More specifically, 5 μg of poly(A)+ RNA, as prepared in Example 1-1 (a) from the CH11-producing hybridoma, were added to 30 μl of reaction mixture (50 mM tris-hydrochloric acid [pH 8.3], 6 mM magnesium chloride, 40 mM potassium chloride, 2 mM dATP, 2 mM dGTP, 2 mM dTTP, 2 μg vector primer [3'-oligo(dT)-tailed, pcDV-1]: Pharmacia) containing 75 units of reverse transcriptase (Seikagaku Kogyo, Co., Ltd.) derived from Avian myeloblastosis virus (AMV). The resulting mixture was incubated at 37°C for 30 minutes.

After this time, an equivalent volume of phenol-chloroform (1:1, v/v) was added to the reaction mixture and thoroughly mixed. The resulting mixture was centrifuged (10,000 x g, room temperature, 5 minutes) and the aqueous layer was recovered (this procedure of extracting with phenol-chloroform and recovering the aqueous supernatant is referred hereinafter as "phenol-chloroform extraction"). To the resulting aqueous layer were added 35 µl of 4 M ammonium acetate and 140 µl of ethanol, and the resulting mixture was cooled at -70°C for 15 minutes, then centrifuged (10,000 x g, 4°C, 15 minutes). The pellet was washed with a 75% (v/v) solution of ethanol and then dried under reduced pressure.

The dried precipitate was then dissolved in 13 µl of distilled water, and then 5.6 µl of terminal transferase reaction mixture [140 mM sodium cacodylate, 30 mM tris-hydrochloric acid (pH 6.8), 1 mM cobalt chloride, 0.5 mM DTT, 0.3 µg polyadenylic acid (polyA, Pharmacia), 0.2 mM dCTP] was added and the resulting reaction mixture was incubated at 37°C for 5 minutes. Terminal deoxynucleotidyl transferase (21 units, Pharmacia) was then added, in accordance with the supplier's instructions, and the reaction was allowed to proceed for 5 minutes. The reaction mixture was then subjected to phenol-chloroform extraction. Then, 20 µl of 4 M ammonium acetate and 80 µl of ethanol were added to the recovered aqueous layer, and the mixture was cooled at -70°C for 15 minutes, then centrifuged (10,000 x g at 4°C for 15 minutes). The pellet was washed with a 75% (v/v) solution of ethanol and dried under reduced pressure.

The DNA precipitate obtained in this way was dissolved in 30 µl of reaction mixture [10 mM tris-hydrochloric acid (pH 7.5), 60 mM sodium chloride, 7 mM magnesium chloride], and 30 units of restriction enzyme HindllI were added to the resulting solution. In general, where a restriction enzyme is used, but no buffer is specified, then the buffer which is used is the buffer supplied with the enzyme. In the case where DNA is digested with two enzymes, digestion is carried out with the two enzymes sequentially. After the first digestion, the DNA is precipitated, resuspended and then digested with the second enzyme. Precipitation and resuspension techniques are well known in the art (c.f. Maniatis et al., supra). All of the restriction enzymes and buffers used in the present Examples were supplied by Takara Schuzo.

The DNA was allowed to be digested at 37°C overnight in the digestion solution. Subsequently, the reaction mixture was subjected to phenol-chloroform extraction. Then, 35  $\mu$ l of 4 M ammonium acetate and 140  $\mu$ l of ethanol were added to the recovered aqueous layer, and the mixture was cooled at -70°C for 15 minutes. The mixture was centrifuged (10,000 x g, 4°C x 15 minutes) to precipitate the DNA, and the resulting pellet was washed with a 75% (v/v) solution of ethanol and dried under reduced pressure. The thus prepared precipitate DNA was used as a cDNA sample in subsequent procedures

In parallel, plasmid DNA from the vector pcDL-SRα296 [c.f. Takebe, Y et al., (1989), "JIKKEN IGAKU (Experimental Medicine)", 7, pp. 95-99] was digested with the restriction enzyme Pstl. The product of the digestion was treated with dGTP and terminal deoxynucleotidyl transferase (Pharmacia), in order to add oligo dG to the 3' terminal end, as follows:

pcDL-SRa296 DNA (100µg, present in 50µl) was added to 10µl of 10x terminal deoxynucleotidyl transferase buffer [1x buffer: 1.4 M sodium cacodylate, 0.3M Tris-HCI, (pH 7.6), 10µl of DTT (1mM), 20µl of 0.1mM <sup>3</sup>H-dGTP (Dupont) and 10µl of terminal transferase (210 IU, Pharmacia)]. The mixture was incubated for 40 minutes at 37°C, and then mixed with an equal volume of TE buffer-saturated phenol. After standing, the aqueous layer was removed and subjected to a phenol-chloroform extraction. After both of the phenol and phenol-chloroform extractions had been performed, then the DNA was precipitated using ethanol and resuspended in 50µl of TE buffer.

The total precipitated DNA was digested with the restriction enzyme HindIII, and the products of the digestion were separated by gel electrophoresis on a 1.8% (w/v) agarose gel. A band of 800 bp was excised from the gel, and extracted

from the gel using a GENECLEAN kit (Funakoshi) according to the manufacturer's instructions. The resulting DNA was dissolved in 100 µl of TE buffer, and 100µl of ethanol was added. The final concentration of the DNA was 0.09 µp/µl.

The resulting product yielded a linker-DNA in which oligo (dG) is attached to the SRα promoter (c.f. Figure 1, which is a schematic view of the construction of a cDNA library to enable cloning of DNA encoding the total length of each subunit of CH11. Figure 2 is a diagram showing the process of cloning and amplifying DNA encoding the total length of each subunit of CH11).

The precipitated, dried, cDNA sample, prepared above, was dissolved in 10  $\mu$ l TE buffer [10 mM tris-hydrochloric acid (pH 7.5), 1 mM EDTA]. A portion of the resulting solution (1  $\mu$ l) was added to reaction buffer [10 mM, tris hydrochloric acid (pH 7.5), 1 mM EDTA, 100 mM sodium chloride] containing 0.08 pmol of the linker-DNA prepared above. The resulting mixture was heated at 65°C for 5 minutes and then incubated at 42°C for 30 minutes. After this time, 10  $\mu$ l of 10x ligase buffer [10 mM ATP, 660 mM tris-hydrochloric acid (pH 7.5), 66 mM magnesium chloride, 100 mM DTT], 76  $\mu$ l of distilled water and 1  $\mu$ l of 10 m M  $\beta$ -nicotinamide adenine dinucleotide (NAD, Boehringer Mannheim) were added to the reaction mixture, and the resulting mixture was cooled on ice for 10 minutes. *E. coli* DNA ligase (8.4  $\mu$ g equivalent, Pharmacia) was then added to the cooled reaction mixture, and the whole was incubated at 12°C, overnight.

After this incubation, 2 µl of nucleotide solution (2 mM dATP, 2 mM dCTP, 2 mM dGTP, 2 mM dTTP), 0.5 µl of 10 mM NAD, 42 µg equivalent of *E. coli* DNA ligase (Pharmacia), 4.1 units of DNA polymerase I (Pharmacia), and 5.5 units of ribonuclease H (Pharmacia) were added to the reaction mixture. The resulting mixture was then incubated at 12°C for one hour and then at 22°C for a further hour. The cDNA library prepared in this way was stored at -20°C until it was needed.

#### (3-2) Cloning by PCR

#### a) Preparation of primer

In the case of the H chain, the amino acid sequence of the variable region of the H chain of CH11, as determined in Example 2, was compared with the antibody amino acid sequence database prepared by Kabat et al. [see Kabat E. A. et al., (1991), in "Sequences of Proteins of Immunological Interest Vol. II", U. S. Department of Health and Human Services]. It was determined that the H chain (µ chain) of CH11 was sub class 2A. Therefore, an oligonucleotide primer was synthesised such that it would hybridise with a part of the 5'-non-translated region of the DNA coding for mouse H chain, sub class 2a. The oligonucleotide primer which was selected had the sequence: 5'-CTAAGGGAAT TC-CGCCTCTC CTCAGACACT GAA-3' (H5-1, SEQ ID NO. 17 of the sequence listing).

An oligonucleotide primer was also designed that would hybridise with a part of the 3' non-translated region of the CH11 H-chain. The design of the olignucleotide was based on the nucleotide sequence of the DNA coding for the mouse immunoglobulin M chain constant region reported by Goldberg, et al. [see Goldberg, I.G., et al., (1981), Gene 15, 33-42], and the sequence which was selected was: 5'-TTTTACTCTA GAGACCCAAG GCCTGCCTGG TTGA-3' (H3-1; SEQ ID NO. 18 of the sequence listing).

For the L chain, the amino acid sequence of the variable region of the L chain of CH11, as determined in Example 2, was compared with the antibody amino acid sequence database prepared by Kabat and co-workers (supra). It was found that the L chain of CH11 was sub-class  $\kappa 2$ . Therefore, an oligonucleotide primer was designed such that it would hybridise with a part of the 5'-terminal, non-translated region of the DNA coding for mouse L chain, sub-class  $\kappa 2$ . The oligonucleotide primer which was selected had the sequence: 5'-AAATAGGAAT TCCAGTCTCC TCAGGCTGTC TCC-3' (L5-1; SEQ ID NO. 19 of the sequence listing).

An oligonucleotide primer was also designed that would hybridise with a part of the 3' non-translated region. The design of the olignucleotide was based on the nucleotide sequence of the DNA coding for the mouse immunoglobulin  $\kappa$  chain constant region registered under the registration name MUSIGB1L1 (Accession No. D14630). The sequence used was: 5'-ATGATCTCTA GAGTGGTGGC ATCTCAGGAC CT-3' (L3-1; SEQ ID NO. 20 of the sequence listing).

In the case of the J chain, there is no variable region and both the sequence of the DNA coding for the J chain, and the amino acid sequence of the J chain are known [c.f. Cann, G.M., et al., (1982), Proc. Natl. Acad. Sci. USA, 79, 6656-6660]. Based on this finding, oligonucleotide primers were synthesised that would hybridise with a part of the 5' and 3' non-translated regions of the DNA coding for the J chain. These oligonucleotides had the sequences: 5'-TT-GCGGAATT CCTCACCTGT CCTGGGGTTA TT-3' (J5-1; SEQ ID NO. 21 of the sequence listing) and 5'-ATTGCCTCTA GAGCCTCTAA GGACAACGAC CT-3' (J3-1; SEQ ID NO. 22 of the sequence listing).

These oligonucleotide primers were all synthesised using an automatic DNA synthesiser 380 B (Perkin Elmer, Japan) by the phosphoamidite method [see Mattrucci, M. D. and Caruthers, M. H. (1981), J. Am. Chem. Soc., 103, 3185-3191]. After synthesis was complete, each primer was cleaved from the support and deprotected, and then freeze dried. The resulting product was dissolved in distilled water and stored at -20°C until it was needed.

#### b) Amplification of target gene by PCR

PCR reaction solution [10 mM tris-hydrochloric acid (pH 8.3), 50 mM potassium chloride, 1.5 mM magnesium chloride, 2.5 mM dATP, 2.5 mM dCTP, 2.5 mM dCTP, 2.5 mM dTTP] was prepared, and 0.1 µl of the cDNA library described in Example 4-1, 1 unit of Taq DNA polymerase (Perkin Elmer, Japan) and 15 pmol of the oligonucleotide primer (prepared in 3-2 a) were added to 100 µl of the PCR reaction solution and heated at 94°C for 2 minutes. The resulting mixture was then subjected to a heat cycle of 94°C for one minute, 55°C for one minute and 72°C for 2 minutes. This cycle was repeated 30 times. After the last cycle, the solution was kept at 72°C for a further 10 minutes.

The combinations of the primers that were used in the respective reactions are as follows:

H5-1 and H3-1 (for H chain); L5-1 and L3-1 (for L chain); and J5-1 and J3-1 (for J chain).

#### c) Assay of PCR product

After the PCR reaction in b) had been performed, a portion of the reaction mixture was analysed by gel electrophoresis on a 0.8% (w/v) agarose gel in the case of the H chain. For the L and J chains, a 1.5% (w/v) agarose gel (agarose was obtained from FMC Bioproducts) was used. The product of the PCR reaction was a band of approximately 1900 bp for the H chain, 800 bp for the L chain and 650 bp for the J chain. The band sizes were estimated by comparison with molecular weight markers run on the same gel

#### d) Cloning of PCR product

Each of the PCR products obtained in b) was ligated into a plasmid vector, using a eukaryote TA cloning kit (Invitrogen). More specifically, 60 ng of pCR3 vector (included in the kit) and four units of T4 DNA ligase were added to ligase reaction buffer [6 mM tris-hydrochloric acid (pH 7.5), 6 mM magnesium chloride, 5 mM sodium chloride, 7 mM β-mercaptoethanol, 0.1 mM ATP, 2 mM DTT, 1 mM spermidine, 0.1 mg/ml bovine serum albumin], containing a portion of the PCR reaction mixture. The volume of the PCR reaction mixture was selected such that it contained about 10 ng of the desired PCR product, as estimated by get electrophoresis. The resulting mixture was incubated at 14°C for 15 hours.

A portion of the ligase reaction mixture (2μl) was mixed with 50 μl of *E. coli* cells, strain TOP10F' (included in the kit), made competent by the addition of 2 μl of 0.5 M β-mercaptoethanol. The resulting mixture was placed on ice for 30 minutes, warmed at 42°C for 30 seconds, then placed on ice again for 2 minutes. SOC medium (500 μl, as described above) was then added to this mixture, and the resulting mixture was cultured at 37°C with rotational shaking (110 rpm) for one hour. The culture liquid was then spread onto L-broth agar medium plates containing 100 μg/ml of ampicillin and cultured at 37°C overnight. Ampicillin-resistant colonies which appeared were then scraped off with a platinum pick and cultured in 5 ml of L-broth medium containing 100 μg/ml of ampicillin at 37°C overnight. These cultures were centrifuged to precipitate cells which were then used to prepare plasmid DNA by the alkaline lysis method (Maniatis et al., supra).

Three of the resulting plasmids were designated pCR3-H123 (the plasmid including H chain-coding cDNA), pCR3-L103 (the plasmid including L chain-coding cDNA) and pCR3-J1123 (the plasmid including J chain-coding cDNA). Competent cells of *E. coli* strain DH5α (Gibco) were transformed with one of the plasmids pCR3-H123, pCR3-L103 or pCR3-J1123 and the resulting transformants were deposited at the Research Institute of Life Science and Technology of the Agency of Industrial Science and Technology on February 28, 1996 under the deposit Nos. FERM BP-5427, FERM BP-5428 and FERM BP-5429, respectively. DNA encoding the H, L and J chains of CH11 are readily prepared from these strains by well known methods.

#### **EXAMPLE 4**

30

Determination of Total Nucleotide Sequence of the cDNA Coding for CH11 H Chain, L Chain and J chains

### (4-1) Determination of nucleotide sequence of DNA

The mouse immunoglobulin M chain consists of an N-terminal variable region containing about 110 residues and a constant region containing about 470 residues, adjacent to the variable region. The mouse immunoglobulin K chain consists of an N-terminal variable region containing about 110 residues and a constant region containing 107 residues adjacent the variable region. It was predicted that the complete nucleotide sequences of the cDNAs coding for the

CH11 H chain and L chain would consist of nucleotide sequences coding for known constant regions and which were ligated to nucleotide sequences coding for the variable regions of the chains, as identified in Example 2 [c.f. Kabat E. A. et. al., (1991), in \*Sequences of Proteins of Immunological Interest Vol. II\*, U.S. Department of Health and Human Services].

The nucleotide sequence encoding the J chain of CH11 was presumed to be the same as that of the known J chain sequence.

Based on these presumed nucleotide sequences, oligonucleotide primers of 20 nucleotides in length were synthesised, corresponding to sequences of the H, L and J chains, separated by coding intervals of 60 to 200 bp. These primers were used for sequence analysis.

The sequences of the synthesised oligonucleotide primers were as follows: For the H chain:

- 5'-TGGGGCCTCA GTGAAGATAT -3' (SHF-2; SEQ ID NO. 23 of the sequence listing)
- 5'-CAATGGTGGT ACTGGCTACA -3' (SHF-3; SEQ ID NO. 24 of the sequence listing)
- 5'-TGACATCTGA GGACTCTGCA -3' (SHF-4; SEQ ID NO. 25 of the sequence listing)
- 5'-TCCTCAGAGA GTCAGTCCTT -3' (SHF-6; SEQ ID NO. 26 of the sequence listing)
- 5'-TCCTTCACCT GGAACTACCA -3' (SHF-7; SEQ ID NO. 27 of the sequence listing)
- 5'-TCCCAAGAGC ATCCTTGAAG -3' (SHF-8; SEQ ID NO. 28 of the sequence listing)
- 5'-AGATCTGCAT GTGCCCATTC -3' (SHF-9, SEQ ID NO. 29 of the sequence listing)
- 5'-TCTAAACTCA TCTGCGAGGC -3' (SHF-10; SEQ ID NO. 30 of the sequence listing)
- 5'-GGTGACCATC GAGAACAAAG -3' (SHF-11; SEQ ID NO. 31 of the sequence listing)
- 5'-AGGGGTCTCA CCTTCTTGAA -3' (SHF-12; SEQ ID NO. 32 of the sequence listing)
- 5'-TCCTTTGCCG ACATCTTCCT -3' (SHF-13; SEQ ID NO. 33 of the sequence listing)
- 5'-GTGTGTACTG TGACTCACAG -3' (SHF-15; SEQ ID NO. 34 of the sequence listing)

45

5'-AACTGAACCT GAGGGAGTCA -3' (SHF-16; SEQ ID NO. 35 of the sequence listing) 5'-AACTCTTGCC CCAAGAGAAG -3' (SHF-17; SEQ ID NO. 36 of the sequence listing) 5'-ATCCTGACTG TGACAGAGGA -3' (SHF-18, SEQ ID NO. 37 of the sequence listing) 5'-ACAAGTCCAC TGGTAAACCC -3' (SHF-19; SEQ ID NO. 38 of the sequence listing) 5'-AGGATATCTT CACTGAGGCC -3' (SHR-1; SEQ ID NO. 39 of the sequence listing) 5'-ATCCACTCAA GGCTCTTTCC -3' (SHR-2; SEQ ID NO. 40 of the sequence listing) 5'-ACTGCAGAGT CCTCAGATGT -3' (SHR-3; SEQ ID NO. 41 of the sequence listing) 5'-AGACGGTGAC TGAGGTTCTT -3' (SHR-4; SEQ ID NO. 42 of the sequence listing) 5'-CAGGTGAAGG AAATGGTGCT -3' (SHR-5; SEQ ID NO. 43 of the sequence listing) 5'-ATGCTCTTGG GAGACAGCAA -3' (SHR-6; SEQ ID NO. 44 of the sequence listing) 5'-CTCTGTTTTT GCCTCCGTAG -3' (SHR-7; SEQ ID NO. 45 of the sequence listing) 5'-TGGCCTCGCA GATGAGTTTA -3' (SHR-8; SEQ ID NO. 46 of the sequence listing) 5'-CCTTTGTTCT CGATGGTCAC -3' (SHR-9; SEQ ID NO. 47 of the sequence listing) 5'-TGTGGAGGAC ACGTTCTTCA -3' (SHR-10; SEQ ID NO. 48 of the sequence listing) 5'-ACTTTGAGAA GCCCAGGAGA -3' (SHR-12; SEQ ID NO. 49 of the sequence listing) 5'-AGATCCCTGT GAGTCACAGT -3' (SHR-13; SEQ ID NO. 50 of the sequence listing) 5'-AGCAGGTGGA TGTTTGTGCA -3' (SHR-14; SEQ ID NO. 51 of the sequence listing) 35 5'-TGAAGCCACT GCACACTGAT -3' (SHR-15; SEQ ID NO. 52 of the sequence listing) 5'-AGTTCCATTC CTCCTCTGTC -3' (SHR-16; SEQ ID NO. 53 of the sequence listing) 5'-TGTGTCAGAC ATGATCAGGG -3' (SHR-18, SEQ ID NO. 54 of the sequence listing)

For the L chain:

50

5'-TGAAGTTGCC TGTTAGGCTG -3' (SLF-1; SEQ ID NO. 55 of the sequence listing)
5'-CTTGGAGATC AAGCCTCCAT -3' (SLF-2; SEQ ID NO. 56 of the sequence listing)
5'-GCTGAGGATC TGGGAGTTTA -3' (SLF-3; SEQ ID NO. 57 of the sequence listing)
5'-GATGCTGCAC CAACTGTATC -3' (SLF-4; SEQ ID NO. 58 of the sequence listing)
5'-CGACAAAATG GCGTCCTGAA -3' (SLF-5; SEQ ID NO. 59 of the sequence listing)
5'-ACGTTGACCA AGGACGAGTA -3' (SLF-6; SEQ ID NO. 60 of the sequence listing)

- 5'-ATCTGCAAGA GATGGAGGCT -3' (SLR-2; SEQ ID NO. 61 of the sequence listing)
- 5'-ACCCCAGAAA ATCGGTTGGA -3' (SLR-3, SEQ ID NO. 62 of the sequence listing)
- 5'-CCGGAGGAAC ATGTGTACTT -3' (SLR-4; SEQ ID NO. 63 of the sequence listing)
- 5'-TCGTTCATAC TCGTCCTTGG -3' (SLR-6; SEQ ID NO. 64 of the sequence listing)
- 5'-CATCTCAGGA CCTTTGTCTC -3' (SLR-7; SEQ ID NO. 65 of the sequence listing)

For the J chain:

1Ŏ

- .5'-CACCTGTCCT GGGGTTATTT -3' (SJF-1; SEQ ID NO. 66 of the sequence listing)
- 5'-AGACAAGATG AAGACCCACC -3' (SJF-2; SEQ ID NO. 67 of the sequence listing)
- 5'-AAGCGACCAT TCTTGCTGAC -3' (SJF-3; SEQ ID NO. 68 of the sequence listing)
- 5'-ATATCTCTGA TCCCACCTCC -3' (SJF-8; SEQ ID NO. 69 of the sequence listing)
- 5'-GAAATGCGAT CCTGTGGAAG -3' (SJF-5, SEQ ID NO. 70 of the sequence listing)
- 5'-CTATACCACT ATGGTCCCAC -3' (SJF-6; SEQ ID NO. 71 of the sequence listing)
- 5'-AGAAGCAGGT GGGTCTTCAT -3' (SJR-2; SEQ ID NO. 72 of the sequence listing)
- 5'-TAGAGGTAAC TCGGGTACAC -3' (SJR-3; SEQ ID NO. 73 of the sequence listing)
- 5'-AAGTTCCTTC TCAGTGGGGA -3' (SJR-8; SEQ ID NO. 74 of the sequence listing)
- 5'-GGTGGCAGTA ACAACCTGAT -3' (SJR-5; SEQ ID NO. 75 of the sequence listing)
- 5'-CATGATACCT AAGTGGGACC -3' (SJR-6; SEQ ID NO. 76 of the sequence listing)

Each oligonucleotide primer was synthesised by the phosphoamidite method using an automatic DNA synthesiser (Model 380B: Perkin Elmer, Japan). Samples for sequence analysis of the H chain were prepared using DNA from plasmid pCR3-H123. Samples for sequence analysis of the L chain were prepared using DNA from plasmid pCR3-L103. Samples for sequence analysis of the J chain were prepared using DNA from pCR3-J1123. The PCR reaction was carried out using a Prism Ready Reaction Terminator Cycle Sequencing Kit (Perkin Elmer, Japan), as follows.

pCR3-H123 (1.5  $\mu$ g) and 4.8 pmol of primer (SHF-2) were mixed to a final volume of 16  $\mu$ l in distilled water. A portion of this pCR3-H123/primer mixture (9.5  $\mu$ l) was mixed with 10.5  $\mu$ l of a premix containing Taq DNA polymerase. All of this procedure was in accordance with the instructions in the kit. The resulting mixture was placed in an automatic reactor (Catalyst: Perkin Elmer, Japan). The reaction cycle used was as follows: 95°C for 30 seconds, 50°C for 15 seconds and 60°C for 4 minutes, repeated 25 times.

After completion of the reaction cycles, 80  $\mu$ l of sterilised water was added to the resulting solution, and the DNA in the resulting mixture was extracted twice by the phenol/chloroform method. The recovered aqueous layer was mixed with 15  $\mu$ l of 2 M sodium acetate and 300  $\mu$ l of ethanol, followed by centrifugation to recover the precipitate. The precipitate was washed with a 70% (v/v) solution of ethanol and dried under reduced pressure, then dissolved in 3  $\mu$ l of sample solution (4  $\mu$ l 0.25 M EDTA, 100  $\mu$ l formamide and 15  $\mu$ l sterilised water).

Sequencing reactions were run and analysed on a DNA sequencer (Model 373A: Perkin Elmer, Japan), for the 32 H chain primers, the 11 L chain primers and the 11 J chain primers.

The sequence data obtained for each primer were combined and integrated in order to determine the complete nucleotide sequence of the H, L and J chains of CH11. The cDNA nucleotide sequences of each plasmid insert are

shown by SEQ ID NOs. 7, 9 and 11 of the sequence listing, respectively. The amino acid sequences that correspond to these nucleotide sequences are shown by SEQ ID NOs. 8, 10 and 12 of the sequence listing, respectively.

#### (4-2) Primary structure of the H chain of CH11

The nucleotide sequence of the H chain variable region, shown as nucleotide Nos. 32 to 379 of SEQ ID NO. 15 of the sequence listing, was found to be identical with that of the nucleotide Nos. 58 to 405 of SEQ ID NO 7.

The amino acid sequence shown as amino acid Nos. 117 to 571 of SEQ ID NO. 8 was found to be identical with the amino acid sequence in the H chain constant region derived from mouse IgM, when compared with the database of antibody amino acid sequences [Kabat E.A. et. al., supra).

The amino acid sequence shown as amino acid Nos. -19 to -1 of SEQ ID NO. 8 was concluded to be a signal sequence of the H chain of CH11.

The nucleotide sequence shown as nucleotide Nos. 406 to 1770 of SEQ ID NO. 7 was found to be identical with that of the H chain constant region of mouse IgM.

Based on these results, the total nucleotide sequence could be established, together with the total amino acid sequence.

#### (4-3) Primary structure of CH11 L chain

20

25

30

45

The nucleotide sequence of the L chain variable region, shown as nucleotide Nos. 29 to 364 of SEQ ID NO. 16 in the sequence listing, was found to be identical with that of nucleotide Nos. 58 to 393 of SEQ ID NO. 9.

The amino acid sequence shown as amino acid Nos. 113 to 219 of SEQ ID NO. 10 was found to be identical with the amino acid sequence in the mouse xL chain constant region, when compared with Kabat's database of antibody amino acid sequences.

The amino acid sequence shown as amino acid Nos. -19 to -1 of SEQ ID NO. 10 was concluded to be a signal sequence for the L chain.

The nucleotide sequence shown as nucleotide Nos. 394 to 714 of SEQ ID NO. 9 was established to be completely identical with that in the mouse κL chain constant region.

Based on these results, the total nucleotide sequence could be established, together with the total amino acid sequence.

#### (4-4) Primary structure of J chain of CH11

The amino acid sequence shown as amino acid Nos. 1 to 137 of SEQ ID NO. 12 was compared with the antibody amino acid sequence database, and found to be identical to the known mouse J chain.

The nucleotide sequence shown as nucleotide Nos. 67 to 477 of SEQ ID NO. 11 was found to be identical with that of the known mouse J chain.

The amino acid sequence shown as amino acid Nos. -22 to -1 of SEQ ID NO. 12 was concluded to be a signal sequence for the Jichain of CH11

Based on these results, the total nucleotide sequence could be established, together with the total amino acid sequence.

#### (4-5) Determination of Complementarity Determining Regions (CDR)

Both the position and the amino acid sequence of each CDR in the variable regions of the H chain and L chain of CH11, determined as described above, were identified by comparison with Kabat's antibody amino acid sequence database (supra). This database shows that the amino acid chain length of the framework area in the variable region is substantially constant throughout different antibodies, provided that the sub-type is the same, and provided that the the amino acid sequences have some common characteristics. However, the CDR's, present between such framework regions, are sequences specific to each antibody.

By comparison of the amino acid sequence of the variable region of CH11 H chain with the sequence of mouse μ2a sub type, the CDR in the CH11 H chain was shown to be represented by amino acid Nos. 31 to 35 of SEQ ID NO. 8 (CDRH<sub>1</sub>, corresponding to SEQ ID NO. 1 of the sequence listing), 50 to 66 of SEQ ID NO. 8 (CDRH<sub>2</sub>, corresponding to SEQ ID NO. 2 of the sequence listing) and 99 to 105 of SEQ ID NO. 8 (CDRH<sub>3</sub>, corresponding to SEQ ID NO. 3 of the sequence listing).

When the amino acid sequence of the variable region of CH11 L chain was compared to the sequence of the mouse k2 sub-type, the CDR of the L chain was shown to be represented by the amino acid Nos. 24 to 39 of SEQ ID NO. 10 (CDRL<sub>1</sub>, corresponding to SEQ ID NO. 4 of the sequence listing), 55 to 61 of SEQ ID NO. 10 (CDRL<sub>2</sub> corre-

sponding to SEQ ID NO. 5 of the sequence listing) and 94 to 102 of SEQ ID NO. 10 (CDRL<sub>3</sub> corresponding to SEQ ID NO. 6 of the sequence listing).

When the amino acid sequence of the variable region of CH11 L chain was compared to the sequence of the mouse k2 sub-type, the CDR of the L chain was shown to be represented by the amino acid Nos. 24 to 39 (CDRL<sub>1</sub>, corresponding to SEQ ID NO. 4 of the sequence listing), 55 to 61 (CDRL<sub>2</sub>, corresponding to SEQ ID NO. 5 of the sequence listing) and 94 to 102 (CDRL<sub>3</sub>, corresponding to SEQ ID NO. 6 of the sequence listing) of SEQ ID NO. 10 of the sequence listing.

#### EXAMPLE 5

#### Expression of the Genes Coding for each Sub Unit of CH11 in COS-1 Cells

#### (5-1) Construction of expression vector

DNA from the high-expression vector pME18S [see Hara, T, et al., (1992), EMBO J., 11, 1875 et seq.] was digested with the restriction enzymes EcoRI and Xba1. The resulting digestion products were separated by agarose gel electrophoresis on a 0.8% agarose gel. Following electrophoresis the gel was stained with ethidium bromide (0.25 µg/ml) to stain the DNA. A band of approximately 3000 bp was excised from the gel and transferred to a dialysis tube (permeation limit: 12000 to 14000 Da, Gibco) along with 250 µl of TBE agarose gel electrophoresis buffer (TBE buffer: Tris 0.089M, Borate 0.089M, EDTA (pH 8.0) 0.002M) and the tube was sealed. The sealed tube was placed in a submarine type electrophoresis tank containing more of the agarose gel electrophoresis buffer and the DNA was electrophoretically eluted from the gel (150 V, 15 minutes). The dialysis tube was taken out, and the DNA eluate in the tube was recovered and subjected to phenol/chloroform extraction.

In parallel, plasmid pCR3-H123, prepared as described in Example 3 d), and which contained the DNA coding for the CH11 H chain, was digested with the restriction enzymes EcoR1 and Xba1. The 1900 bp EcoRI-Xbal fragment was isolated and purified by agarose gel electrophoresis on a 0.8% gel, as described in 5-1 above. This cDNA fragment was ligated to the 3 kb EcoRI-Xbal fragment of pME18S, isolated as above, using DNA ligation kit version 1 (Takara Shuzo Co., Ltd.).

Plasmid pCR3-L103, prepared in Example 3, containing the DNA coding for the CH11 L chain, was digested with the restriction enzymes EcoR1 and Xba1. An 840 bp EcoRI-Xbal fragment containing the cDNA plasmid insert was isolated and purified by agarose gel electrophoresis on a 0.8% gel, as described in 5-1 above. This cDNA fragment was ligated to the 3 kb EcoRI-Xbal fragment of pME18S obtained above, using DNA ligation kit version 1 (Takara Shuzo Co., Ltd.).

Plasmid pCR3-J1123 prepared in Example 3, containing the DNA coding for the CH11 J chain, was digested with the restriction enzymes EcoR1 and Xba1. A 640 bp EcoRI-Xbal fragment containing the cDNA plasmid insert was isolated and purified by agarose gel electrophoresis on a 0.8% gel, as described in 5-1 above. This cDNA fragment was ligated to the 3 kb EcoRI-Xbal fragment of pME18S obtained above, using DNA ligation kit version 1 (Takara Shuzo Co., Ltd.).

After the ligation reactions had been completed, JM109 *E. coli* competent cells (Takara Shuzo) were transformed using each reaction mixture, and colonies were selected for amplcillin-resistant strains. Plasmid DNA was prepared from the transformed strains by alkaline tysis (Maniatis, *supra*). The resulting plasmid DNA was digested with EcoR1 and Xba1, which was then followed by agarose gel electrophoresis on a 0.8% gel, to confirm that DNA of the desired size had been cloned.

The expression vector containing the DNA coding for the CH11 H chain was designated pHEX126. The expression vector containing the DNA coding for the CH11 L chain was designated pLEX004, and expression vector containing the DNA coding for the CH11 J chain was designated pJEX004.

#### 5-2 Expression in COS-1 cells

COS-1 cells were transformed with pHEX126, pLEX004 and pJEX004 by electroporation using the GTE-1 apparatus (Shimadzu Corporation). More specifically, COS-1 cells (American Type Culture Collection No. CRL-1650) were cultured in a 225cm<sup>2</sup> culturing flask (Sumitomo Bakelite). The cells were grown to a semiconfluent state in Dulbecco's modified Eagle's minimum essential medium ('DMEM', Nissui Pharmaceutical) containing 10% (v/v) foetal bovine serum (CSL). The medium was removed and the cells were treated twice with 3 ml of trypsin-EDTA solution (Sigma) at 37°C for 3 minutes. The cells were recovered, then washed twice with a phosphate buffered saline (PBS, pH 8.0) buffer (Nissui Pharmaceutical). The washed COS-1 cells were adjusted to a density of 6 x 10<sup>7</sup> cells/ml with PBS (-) buffer (8g NaCl, 0.2g KCl, 1.15g Na<sub>2</sub>HPO<sub>4</sub>, 0.2g KH<sub>2</sub>PO<sub>4</sub> per litre, Nissui Seiyaku Co.).

DNA was prepared from each of the pHEX126, pLEX004 and pJEX004, which encode all three of the sub units

of CH11, using a plasmid maxiprep kit (Maxiprep DNA purification system; Promega). A portion (20 µg) of each plasmid maxiprep was precipitated using ethanol, and the precipitate was dissolved in 20 µl of PBS (-) buffer. The DNA prepared in this way was used for transfection of the COS-1 cells. Any transfections carried out using more than one plasmid used 20 µg of each plasmid.

A suspension of COS-1 cells (20 µl; 1.2 x 10<sup>6</sup> cells) prepared in this way was mixed with 20 µl of each sample, and the resulting mixture was placed in an electroporation cuvette (Shimadzu Corporation) having an electrode interval of 2 mm. The cuvette was placed into the electroporation apparatus and two 600V-30 µsec pulses were applied, with a one second interval between pulses. The mixture of the cells and DNA was added to 10 ml of DMEM containing 10% (v/v) foetal bovine serum, then transferred to a cell culturing plastic dish (diameter: 90 mM; Sumitomo Bakelite) and cultured at 37°C under 7.5% CO<sub>2</sub> for 24 hours. After this time the culture supernatant was removed and the cells were washed with a serum-free DMEM medium. Fresh serum-free DMEM medium was added (10 mls), and culturing continued at 37°C under 7.5% CO<sub>2</sub> for 24 hours. The culture supernatant was then recovered.

The COS-1 cells were transfected using either one plasmid, or a combination of plasmids, as listed below. The culture supernatant was recovered in each case.

#### **EXAMPLE 6**

15

#### Detection of anti-Fas Antibody

The anti-Fas antibody prepared according to the present invention was detected by two methods, separately.

- (1) The first method was Western Blotting. The protein sample was run on an SDS-polyacrylamide gel under the conditions shown below, and the sample proteins separated by electrophoresis (this whole process is known as SDS polyacrylamide gel electrophoresis or 'SDS-PAGE'). The proteins were transferred to a nitrocellulose membrane, and reacted with an antibody specific to the anti-Fas antibody. Cross reaction of the antibody with the target anti-Fas protein is detectable, in the presence of suitable substrates, by light emission on a photographic film.
- (2) The second method measures binding affinity to the Fas antigen.

#### (6-1) Western blotting

The test sample of culture supernatant (1 ml) was dialysed against 5 litres of pure water, then dried under reduced pressure using a centrifugal concentrator (CC-101; Tomy Seiko). The resulting product was added to 10 μl of a sample buffer [2% (w/v) SDS (electrophoresis grade; Bio-Rad), 5% (v/v) β-mercaptoethanol (Sigma), 10% (v/v) glycerol, 0.1% (w/v) bromophenol blue] and mixed thoroughly. The resulting suspension was heated at 100°C for 5 minutes to provide a sample suitable for electrophoresis. The entire electrophoresis sample was loaded into one well of a SDS-polyacrylamide gel (4 to 20% gradient gel, buffer composition per litre: Tris 3.0g, Glycine 14.4g, SDS 10g, pH 8.3), and the gel was run at a constant current of 20 mA (room temperature, one hour).

Once the electrophoresis had been performed, proteins were transferred from the gel to a nitrocellulose membrane,

using the semi-dry blotting method [see Towbin, H, et al., (1979), Proc. Natl. Acad. Sci. USA, 76, 4350 et seq.]. The specific apparatus and conditions used were as follows:

Transfer buffer:

25

20 mM tris, 150 mM glycine,

10% (v/v) methanol

Blotting equipment:

manufactured by Iwaki Glass

Operating conditions:

4°C, 0.2 A (constant current), 1 hour.

Two nitrocellulose membranes for Western blotting were prepared as described above. After Western transfer, the gels were stained silver using a 'Sil Best Kit' (Nakarai Tesuku Kabushiki-Kaisha).

One of the two Western blotting nitrocellulose membranes prepared as above was employed for H chain ( $\mu$  chain) detection and the other for L chain (K chain) detection. The following procedures were used.

After the Western transfer, the nitrocellulose membranes were immersed in an aqueous solution containing 3% (w/v) gelatin (Bio-Rad), 20 mM tris-hydrochloric acid (pH 7.5) and 500 mM of sodium chloride. Membranes were shaken gently at room temperature for one hour (the procedure described since "After Western transfer" is referred to herein as "blocking"). The thus blocked nitrocellulose membranes were immersed in a diluted antibody solution and shaken gently at room temperature for 2 hours. The resulting antibody solutions were prepared by diluting either 2.5  $\mu$ l of peroxidase-labelled goat anti-mouse IgM antibody ( $\mu$  chain-specific: Jackson Immuno Research Laboratories) or 25  $\mu$ l of peroxidase-labelled rat anti-mouse  $\kappa$  chain monoclonal antibody (Zymed Laboratories) with 10 ml of buffer [20 mM tris-hydrochloric acid (pH 7.5), 500 mM sodium chloride] hereinafter referred to as "TBS".

Each nitrocellulose membrane was then immersed in 20 ml of TTBS, which is TBS containing 2% (v/v) Tween 20 (Bio-Rad) and washed by shaking gently at room temperature for 15 minutes. The treated membranes were washed with 20 ml of TTBS, which was then drained away. Residual peroxidase activity on this nitrocellulose membrane was detected using an ECL Western Blotting Detection system (Amersham). More specifically, the substrate in this system emits light during a chemical reaction under the catalytic action of peroxidase. The light emission may be detected on photographic film using an ECL mini camera (Amersham) and instant film (Type 667; Polaroid). The pictures taken were compared with the silver-stained gels to identify the protein bands that were specifically bound to the antibodies.

Antibodies to the mouse M chain cross-reacted with a protein band of approximately 78,000 Da. A band of this size was present in the supernatant of COS-1 cell samples that had been transfected with pHEX126, either singly or with another plasmid. These samples corresponded to [B], [E] and [F] of Example 5.

Antibodies to the mouse K chain cross-reacted with a protein band of approximately 26,000 Da. A band of this size was present in the supernatant of COS-1 cell samples that had been transfected with pLEX004, either singly or with another plasmid. These samples corresponded to [C], [E] and [F] of Example 5.

The antibody produced by the hybridoma was analysed by Western blotting using the same methodology. Bands corresponding to the H and L chain of CH11 from the hybridoma were seen to be the same size as those obtained from the transfected COS-1 cells.

# (6-2) Confirmation of Fas binding ability by ELISA

# (a) Preparation of antigen

The expression vector pME18S-mfas-AIC [see Nishimura, Y., et al., (1995), Mol. Immunol., 154, 4395-4403] encodes a fusion protein consisting of the extracellular region of mouse Fas antigen and the extracellular region of mouse interleukin 3 receptor. The portion of the vector encoding the extracellular region of mouse Fas antigen was replaced with a DNA fragment encoding the extracellular region of human Fas antigen. This new expression vector, phFas-AIC2, encoding a fusion protein consisting of the extracellular region of the human Fas antigen and the extracellular region of the mouse interleukin 3 receptor, was prepared as described below.

Oligonucleotide primers were designed and synthesised in order to allow PCR amplification of DNA coding for the Fas antigen extracellular region. The DNA template used was the plasmid vector pCEV4 [Itoh, N., et al., (1991), Cell, 66, 233-243] which contains the cDNA coding for the human Fas antigen. The sequences of the oligonucleotides selected were as follows:

# 5'-GGGGAATTCC AGTACGGAGT TGGGGAAGCT CTTT-3' (N1; SEQ ID NO.

77 of the sequence listing); and

# 5'-GTTTCTTCTG CCTCTGTCAC CAAGTTAGAT CTGGA-3' (C3N; SEQ ID NO.

78 of the sequence listing).

Oligonucleotide primers were also designed and synthesised in order to allow PCR amplification of the DNA coding for the extracellular region of the mouse interleukin 3 receptor. The DNA template used was the plasmid vector pME18S-mFas-AIC (Nishimara, Y. et al., 1995, Mol. Immunology, 154, 4395-4403). The sequences of the oligonucleotides were as follows:

#### 5'-TCCAGATCTA ACTTGGTGAC AGAGGCAGAA GAAAC-3' (N3N; SEQ ID

NO. 79 of the sequence listing); and

5'-CCCTCTAGAC GCGTCACGTG GGCATCAC-3' (CTN2; SEQ ID NO. 80 of the sequence listing).

The PCR reaction was carried out using the above plasmids, the oligonucleotide primers and the LA PCR kit (Takara Shuzo Co., Ltd.) under the following conditions.

Composition of reaction mixture:

| Plasmid DNA                         | 20 ng         |
|-------------------------------------|---------------|
| Oligonucleotide primers             | 0.5 μg (each) |
| 10-Fold concentration LA PCA buffer | 25 μΙ         |
| dNTP mix                            | 25 μί         |
| Taq polymerase                      | 12.5 units    |

Distilled water was added to make up the final volume to 250 µl; the buffer, dNTP mix and Taq polymerase were included in the kit.

#### Temperature conditions:

20

25

30

35

40

The sample was initially heated at 94°C for 2 minutes. The reaction mixture was then subjected to a heat cycle of 94°C for one minute, 55°C for one minute and 72°C for 2 minutes, and this cycle was repeated 30 times, followed by heating at 72°C for a further 10 minutes.

The products of each PCR reaction were separated by electrophoresis on an 8% polyacrylamide gel (run in TBE buffer, at 100V for 2 hours). A band of approximately 460 bp was excised from the gel, corresponding to the DNA fragment containing the gene coding for the extracellular region of the human Fas antigen. A band of approximately 1300 bp was also excised from the gel, corresponding to the DNA fragment containing the gene coding for the extracellular region of the mouse interleukin 3 receptor. DNA fragments were eluted from the gel as described in Example 5.

The two DNA fragments obtained after the first PCR reaction were used together in a second PCR reaction, along with the oligonucleotide primers C3N and N3N. Each primer hybridises to one of the original fragments. When used in a PCR reaction, the primers amplify a fragment of DNA in which two polypeptide-coding genes are ligated in the same reading frame. The second PCR reaction was carried out under the following conditions:

Composition of reaction mixture:

| Products from the First-run PCR | Entire volume of each |
|---------------------------------|-----------------------|
| Oligonucleotide primers         | 0.1 μg (each)         |

#### (continued)

| 10-Fold concentration LA PCA buffer | 25 µl      |
|-------------------------------------|------------|
| dNTP mix · .                        | 25 μΙ      |
| Taq polymerase                      | 12.5 units |

Distilled water was added to make up the final volume to 250 µl.

The heat cycling conditions were identical to those used in the immediately previous PCR reaction.

A portion of the reaction mixture of the second PCR was loaded and run on an agarose gel, which confirmed that the desired PCR product of approximately 1700 bp had been amplified. The remainder of the reaction mixture was then precipitated using ethanol. The precipitated DNA was digested with the restriction enzymes EcoR1 and Xba1 and the digestion products were separated by agarose gel electrophoresis on a 1% (w/v) agarose gel. A band of approximately 1700 bp was excised from the gel, and the DNA was purified from the gel in a similar manner to that described in Example 5.

In parallel, 2  $\mu g$  of pME18S-mías-AIC DNA were digested with the restriction enzymes EcoR1 and Xba1. The products of the digestion were separated by gel electrophoresis on a 0.8% (w/v) agarose gel, and a band of approximately 3000 bp was excised from the gel. The DNA was isolated and ligated to the 1700 bp PCR product (prepared above) using a DNA ligation kit version 2 (Takara Shuzo Co., Ltd.). The total reaction mixture (10  $\mu$ l) was used to transform JM109 *E. coli* competent cells (Takara Shuzo) and a selection was made for ampicillin-resistant colonies. One such ampicillin resistant transformant was cultured by conventional procedures, and plasmid DNA prepared from the cells by alkaline lysis (Maniatis, supra). The resulting plasmid was designated phFas-AlC2.

phFAS-AIC2 DNA was transfected into COS-1 cells by electroporation, using the GTE-1 apparatus. More specifically, the COS-1 cells were cultured in four 225 cm² culturing flasks (Sumitomo Bakelite). The cells were grown to a semiconfluent state in DMEM containing 10% (v/v) foetal bovine serum (CSL). The medium was removed and the cells were treated twice with 3 ml of trypsin-EDTA solution (Sigma) at 37°C for 3 minutes. The cells were recovered, then washed twice with a PBS (-) buffer (Nissui Pharmaceutical). The washed COS-1 cells were adjusted to a density of 6 x 10<sup>7</sup> cells/ml with PBS (-) buffer.

phFas-AIC2 plasmid DNA was prepared using a plasmid mass preparation kit (Maxiprep DNA Purification System; Promega) and 200 μg of this plasmid DNA was precipitated by ethanol, then dissolved in 200 μl of PBS(-) buffer.

A portion of the cell suspension ( $20 \,\mu$ l;  $1.2 \, x \, 10^6$  cells) and  $20 \,\mu$ l of plasmid solution were mixed, and the resulting mixture was introduced to an electroporation cuvette having an electrode interval of 2 mm. The cuvette was placed into the electroporation apparatus and two 600V-30 $\mu$ sec pulses were applied to the sample, with an interval of 1 second between pulses. This procedure was carried out on ten samples.

The cell-DNA mixtures of the 10 samples were combined and added to 50 ml of DMEM containing 10% (v/v) of foetal bovine serum and the resulting mixture was transferred into a 225 cm² cell culturing flask (Sumitomo Bakelite). The cells were cultured at 37°C under 7.5% CO<sub>2</sub> for 24 hours. After this time, the culture supernatant was removed and the cells were washed with serum-free DMEM medium. Fresh serum-free DMEM medium (50 ml) was then added to the culture, and the cells were cultured at 37°C under 7.5% CO<sub>2</sub> for a further 24 hours. After this time the culture supernatant was recovered.

#### (b) ELISA

20

30

50

55

Aliquots of the COS-1 culture supernatants (100 µl) were pipetted into wells of a 96-well immunoplate (Maxisorb; Nunk) and stored at 4°C overnight. This results in the formation of a solid phase of protein on the inner surface of the well, containing the extracellular region of human Fas antigen. Each well was washed with PBS containing 0.05% (v/v) Tween-20 (EIA grade, Bio-Rad), then 100 µl of PBS containing 0.5% (w/v) of bovine serum albumin (BSA) was added. The plate was left at room temperature for one hour to effect blocking.

Each well was washed with PBS containing 0.05% (v/v) Tween 20, and then a CH11 (standard) prepared in Example 2, along with 100 µl of diluted test sample solutions prepared in Example 5 were pipetted into the wells. The reaction was allowed to continue at room temperature for 4 hours.

The wells were then washed with PBS containing 0.05% (v/v) Tween-20. A portion (100  $\mu$ l) of peroxidase-labelled rat anti-mouse IgM monoclonal antibody (1/2000 dilution, Zymed Laboratories) was pipetted into each well and the reaction allowed to proceed at room temperature for 2 hours.

The wells were then further washed with PBS containing 0.05% ( $\nu\nu$ ) Tween-20. A portion (100  $\mu$ i) of substrate solution (Peroxidase substrate kit ABTS; Bio-Rad) was pipetted into each well to initiate a colour reaction. The absorbency values of each well at 405 nm and 492 nm were measured using a microplate reader and the absorbance reading at 492nm was subtracted from the absorbance reading at 492nm. The values thus obtained were compared to those

of the CH11 standard, to evaluate the ability of the test sample to bind to the protein containing the extracellular region of human Fas antigen.

The results are shown in Table 1 below. As can be seen, binding was observed using supernatants [E] (pHEX126 and pLEX004) and [F] (pHEX126, pLEX004 and pJEX004), prepared in Example 5.

Table 1

| Sample                      | OD <sub>405</sub> - OD <sub>492</sub> |
|-----------------------------|---------------------------------------|
|                             |                                       |
| CH11 Standard               | 0.445                                 |
| PBS '                       | 0.104                                 |
| pHEX126                     | 0.109                                 |
| pLEX004                     | 0.135                                 |
| pJEX 004                    | 0.107                                 |
| pHEX126 + pLEX004           | 0.330                                 |
| pHEX126 + pLEX004 + PJEX004 | 0.202                                 |

50

#### Cytotoxicity Assay

The cytotoxicity of each COS-1 cell culture supernatant prepared in Example 5 was determined by the MTT [3-(4, 5-dimethylthiazol-2-yl)-2,5-diphenyl 2H-tetrazolium bromide] assay method, described below.

The human lymphocyte cell strain HPB-ALL [see Morikawa, S., et al., (1978), Int. J. Cancer, 21, 166-170] was cultured on a RPMI1640 medium (Nissui Pharmaceutical) containing 20 mM HEPES (HEPES: N-2-Hydroxyethylpiper-azine-N'-2-Ethane Sulphonic Acid), 50 μM 2-mercaptoethanol and 10% (v/v) foetal bovine serum (Equitec Bio) under 5% CO<sub>2</sub> at 37°C for 3 days. A portion (75μl) of COS-1 cell culture supernatants prepared in Example 5 were pipetted into wells of 96-well culturing plate and then 25 μl of HPB-ALL cells (adjusted to 2 x 10<sup>5</sup> cells/ml) were added. The cells were cultured at 37°C in the presence of 5% CO<sub>2</sub> for 12 hours. To each well of the dish was added 10 μl of a 5mg/ml aqueous solution of MTT (Sigma) and the plate was incubated at 37°C for 4 hours. After the incubation 100 μl of a solution containing 50% (v/v) N,N-dimethylformamide and 20% (w/v) SDS was added to each well. The absorbency values for each well were read at 590 nm and 620 nm using a microplate reader (Nippon Intermed Ltd.). The absorbance at 620 nm was subtracted from the absorbance at 590 nm. The higher the value, the larger the number of viable cells remaining in the well. The resulting values are given in Table 2 below.

Table 2

| Table 2                     |                                       |
|-----------------------------|---------------------------------------|
| Sample                      | OD <sub>590</sub> - OD <sub>620</sub> |
|                             |                                       |
| PBS                         | 0.864                                 |
| pME 18S                     | 0.881                                 |
| pHEX126 (H-chain)           | 0.876                                 |
| pLEX004 (L-chain)           | 0.887                                 |
| pJEX004 (J-chain)           | 0.883                                 |
| pHEX126 + pLEX004           | 0.176                                 |
| pHEX126 + pLEX004 + pJEX004 | 0.242                                 |

Those COS-1 cell cultures that were transfected with a single plasmid in Example 5 ([A], [B], [C] and [D]) all showed high values, comparable to that of the non-transfected cells. Those cells co-transfected with pHEX126 and pLEX004 ([E] and [F]) showed low values comparable to that of a blank in which no cells were present. From these results, it was found that a cytotoxic substance is produced by co-expression of the DNA coding for the CH11 H chain and CH11 L chain.

#### **EXAMPLE 8**

10

20

#### Comparative Antibody Cytotoxicity (ED<sub>50</sub> Test)

Cytotoxicity of the antibodies of the present invention was evaluated by an  $ED_{50}$  test. As used herein,  $ED_{50}$  is the concentration of antibody at which 50% of a sample of cells expressing the Fas antigen were killed. Prior to measuring  $ED_{50}$ , it was necessary to accurately calculate the concentration of the antibodies under test.

#### 8-1 Determination of Antibody Concentration

Into each well of a 96 well ELISA plate (NUNC) was pipetted 100  $\mu$ l of an anti-mouse IgM antibody solution (0.5  $\mu$ g/ml in 50 mM Na<sub>2</sub>HCO<sub>3</sub>, pH 9.6, purchased from BIOSYS), and the plate was incubated overnight at 4°C. The antibody solution was then discarded and each well was washed four times with PBS containing 0.5% Tween-20 (hereafter referred to as 'PBS-T').

'Super-Block' Blocking Buffer (Pierce) was made up in PBS, in accordance with the manufacturer's instructions and 100 μl of this buffer was pipetted into each well. The plate was then further incubated for four hours at 37°C. After this time, the blocking solution was discarded, and each well was washed four times with PBS-T.

A 100 µl sample of each antibody preparation to be tested was added to each well of the plate. The test samples comprised CH11, and supernatants [E] and [F] of Example 5. Various standard preparations comprising mouse IgM (Zymed) diluted to different concentrations were used. After the samples had been added to the wells, the plate was incubated at 37°C for 4 hours. After this time, the test and standard solutions were discarded, and each well was washed four times with PBS-T.

A sample of horseradish peroxidase-conjugated anti mouse IgM (100  $\mu$ l of a 1/1000 dilution in PBS) was added to each well. This solution was then discarded and each well was washed with PBS-T four times.

A 100 µl sample prepared from a Horseradish Peroxidase Substrate Kit (Biorad) was added to each well and the plate was incubated at room temperature for 30 minutes. After this time, absorbance readings were taken at both 405 and 492 nm using a Microplate reader. The absorbance at 492 nm was then subtracted from the reading at 405 nm.

By using the absorbance values for the standard samples, it was possible to construct a standard curve from which the concentration of each test antibody was able to be determined.

It was then possible to evaluate ED50.

#### (8-2) ED<sub>50</sub> Calculation

The three antibody solutions, of CH11, supernatant [E] (containing H and L chains) and supernatant [F] (containing H, L and J chains) of Example 5, respectively, were incubated with HBP-ALL cells. An MTT assay, described in Example 7, was used to assess how many cells were killed by each antibody solution.

The MTT results for each antibody were calculated as a function of protein concentration obtained in (8-1) above, to determine the  $ED_{50}$  value, taking the MTT as the negative control and the results for HBP-ALL cultured in the absence of antibody as the positive control. Results are shown in Table 3.

Table 3

| Antibody                                       | ED <sub>50</sub> (ng/mi) |
|--|--------------------------|
|  |                          |
| CH11   | 21.2                     |
| Supernatant [E] (pHEX126 and pLEX004)          | . 4.5                    |
| Supernatant [F] (pHEX126, pLEX004 and pJEX004) | 22.9                     |

The above results clearly show that the product contained in supernatant [E] surprisingly possesses approximately 5 times more activity than either CH11 or the product contained in supernatant [F]. It seems likely that an IgM structure is formed by the product contained in supernatant [F], while the product contained in supernatant [E] forms simple antibody pairings and that, under these circumstances, ED<sub>50</sub> is significantly enhanced.

#### Claims

35

40

50

- 1. A recombinant protein, the protein comprising at least one region corresponding to an immunoglobulin variable region, wherein the at least one region enables the protein to recognize and specifically bind to an antigen, the antigen being human Fas, and wherein the protein has substantially no more immunogenicity in a human patient than a human antibody.
- 2. A protein according to claim 1, which consists essentially of only one variable region.
  - 3. A protein according to claim 1, which consists essentially of two variable regions, one of the variable regions corresponding to an H chain variable region and the other to an L chain variable region.
- A protein according to claim 1 or 3, wherein the variable regions are connected by a flexible peptide linkage.
  - A protein according to claim 1, 3 or 4, having at least two of the variable regions, the variable regions being derived from a single monoclonal antibody.
- 26 6. A protein according to claim 5, wherein the variable regions are integrally bound with human constant regions.
  - 7. A protein according to claim 5 or 6, wherein the variable regions correspond to either an H chain variable region or to an L chain variable region, and are individually bound to an H chain constant region or an L chain constant region, respectively.
  - A protein according to any of claims 5 to 7, wherein the variable regions are each respectively a part of a larger polypeptide and the two polypeptides associate to form an antibody heterodimer.
  - A protein according to any of claims 5 to 8, wherein the variable regions are either identical with or correspond closely to those found in CH11.
  - 10. A genetically engineered immunoglobulin protein which specifically binds to human Fas, wherein the immunoglobulin protein consists essentially of an H chain subunit and an L chain subunit, the H chain subunit comprising an amino acid sequence represented by the following general formula (I):

$$-FRH_{1}-CDRH_{1}-FRH_{2}-CDRH_{2}-FRH_{3}-CDRH_{3}-FRH_{4}- \tag{I}$$

wherein FRH<sub>1</sub> represents an amino acid sequence comprising 13 to 30 amino acid residues, CDRH<sub>1</sub> represents the amino acid sequence of SEQ ID NO. 1, FRH<sub>2</sub> represents an amino acid sequence comprising 14 amino acid residues, CDRH<sub>2</sub> represents the amino acid sequence of SEQ ID NO. 2, FRH<sub>3</sub> represents an amino acid sequence comprising 32 amino acid residues, CDRH<sub>3</sub> represents the amino acid sequence of SEQ ID NO. 3, and FRH<sub>4</sub> represents an amino acid sequence comprising 11 amino acid residues, each of the amino acid sequences being linked to the next *via* a peptide bond;

said L chain subunit comprising an amino acid sequence represented by the following general formula (II):

wherein FRL<sub>1</sub> represents an amino acid sequence comprising 23 amino acid residues, CDRL<sub>1</sub> represents the amino acid sequence of SEQ ID NO. 4, FRL<sub>2</sub> represents an amino acid sequence comprising 15 amino acid residues, CDRL<sub>2</sub> represents the amino acid sequence of SEQ ID NO. 5, FRL<sub>3</sub> represents an amino acid sequence

comprising 32 amino acid residues, CDRL<sub>3</sub> represents the amino acid sequence of SEQ ID NO. 6, and FRL<sub>4</sub> represents an amino acid sequence comprising 10 amino acid residues, each of the amino acid sequences being linked to the next *via* a peptide bond.

- A protein according to claim 10, when the H chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 116 in SEQ ID NO. 8.
  - 12. A protein according to claim 10 or 11, when the L chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 112 in SEQ ID NO. 10.
  - 13. A protein according to claim 11 or 12, wherein the H chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 571 in SEQ ID NO. 8.
  - 14. A protein according to claim 11, 12 or 13, wherein the L chain subunit comprises the amino acid sequence represented by amino acids No. 1 to 219 in SEQ ID NO. 10.
  - 15. RNA encoding a protein according to any preceding claim.

10

15

20

25

40

45

50

- 16. DNA encoding a protein according to any of claims 1 to 14.
- 17. DNA encoding a peptide of formula (I) as defined in claim 10.
- DNA according to claim 17, which comprises the nucleotide sequence represented by nucleotides No. 58 to 405 in SEQ ID NO. 7.
- 19. DNA which hybridizes with DNA according to claim 18, a sense strand corresponding to the hybridizing DNA encoding an immunoglobulin H chain subunit capable of specifically binding human Fas together with an L chain subunit comprising an amino acid sequence of general formula (II) as defined in claim 10.
- 20. Hybridizing DNA according to claim 19 which hybridizes at 60 to 70°C and in 6 x SSC.
  - 21. DNA coding for an L chain subunit comprising an amino acid sequence represented by general formula (II) as defined in claim 10.
- 22. DNA according to claim 21, which comprises the nucleotide sequence represented by nucleotides No. 58 to 393 in SEQ ID NO. 9.
  - 23. DNA which hybridizes with DNA according to claim 22, a sense strand corresponding to the hybridizing DNA encoding an immunoglobulin L chain subunit capable of specifically binding human Fas together with an H chain subunit comprising an amino acid sequence of general formula (I) as defined in claim 10.
  - 24. Hybridizing DNA according to claim 23 which hybridizes at 60 to 70°C and in 6 x SSC.
  - 25. A vector comprising DNA according to any of claims 16 to 24.
  - 26. A vector according to claim 25 which is an expression vector.
  - 27. A vector selected from pCR3-H123 and pCR3-L103.
  - 28. A host cell transformed with an expression vector according to any of claims 25 to 27.
  - 29. E. coli pCR3-H123 (FERM BP-5247).
  - 30. E. coli pCR3-L103 (FERM BP-5248).

31. A method for producing an immunoglobulin protein which specifically recognizes human Fas antigen comprising culturing a cell according to any of claims 28 to 30 under conditions which enable expression of DNA encoding the immunoglobulin H chain or L chain subunit contained in the vector, and recovering the immunoglobulin protein

from the culture.

10

15

30

35

- 32. The use of CDR's selected from CDRH<sub>1</sub>, CDRH<sub>2</sub>, CDRH<sub>3</sub>, CDRL<sub>1</sub>, CDRL<sub>2</sub> and CDRL<sub>3</sub>, as defined in claim 10, and combinations thereof, in the construction of humanized antibodies.
- 33. The use of DNA encoding CDR's selected from CDRH<sub>1</sub>, CDRH<sub>2</sub>, CDRH<sub>3</sub>, CDRL<sub>2</sub> and CDRL<sub>3</sub>, as defined in claim 10, and combinations thereof, in the construction of DNA encoding humanized antibodies.
- 34. Use of a protein according to any of claims 1 to 14 in the preparation of a medicament for the treatment of an autoimmune disease.
- 35. Use according to claim 34, wherein the autoimmune disease is rheumatism.
